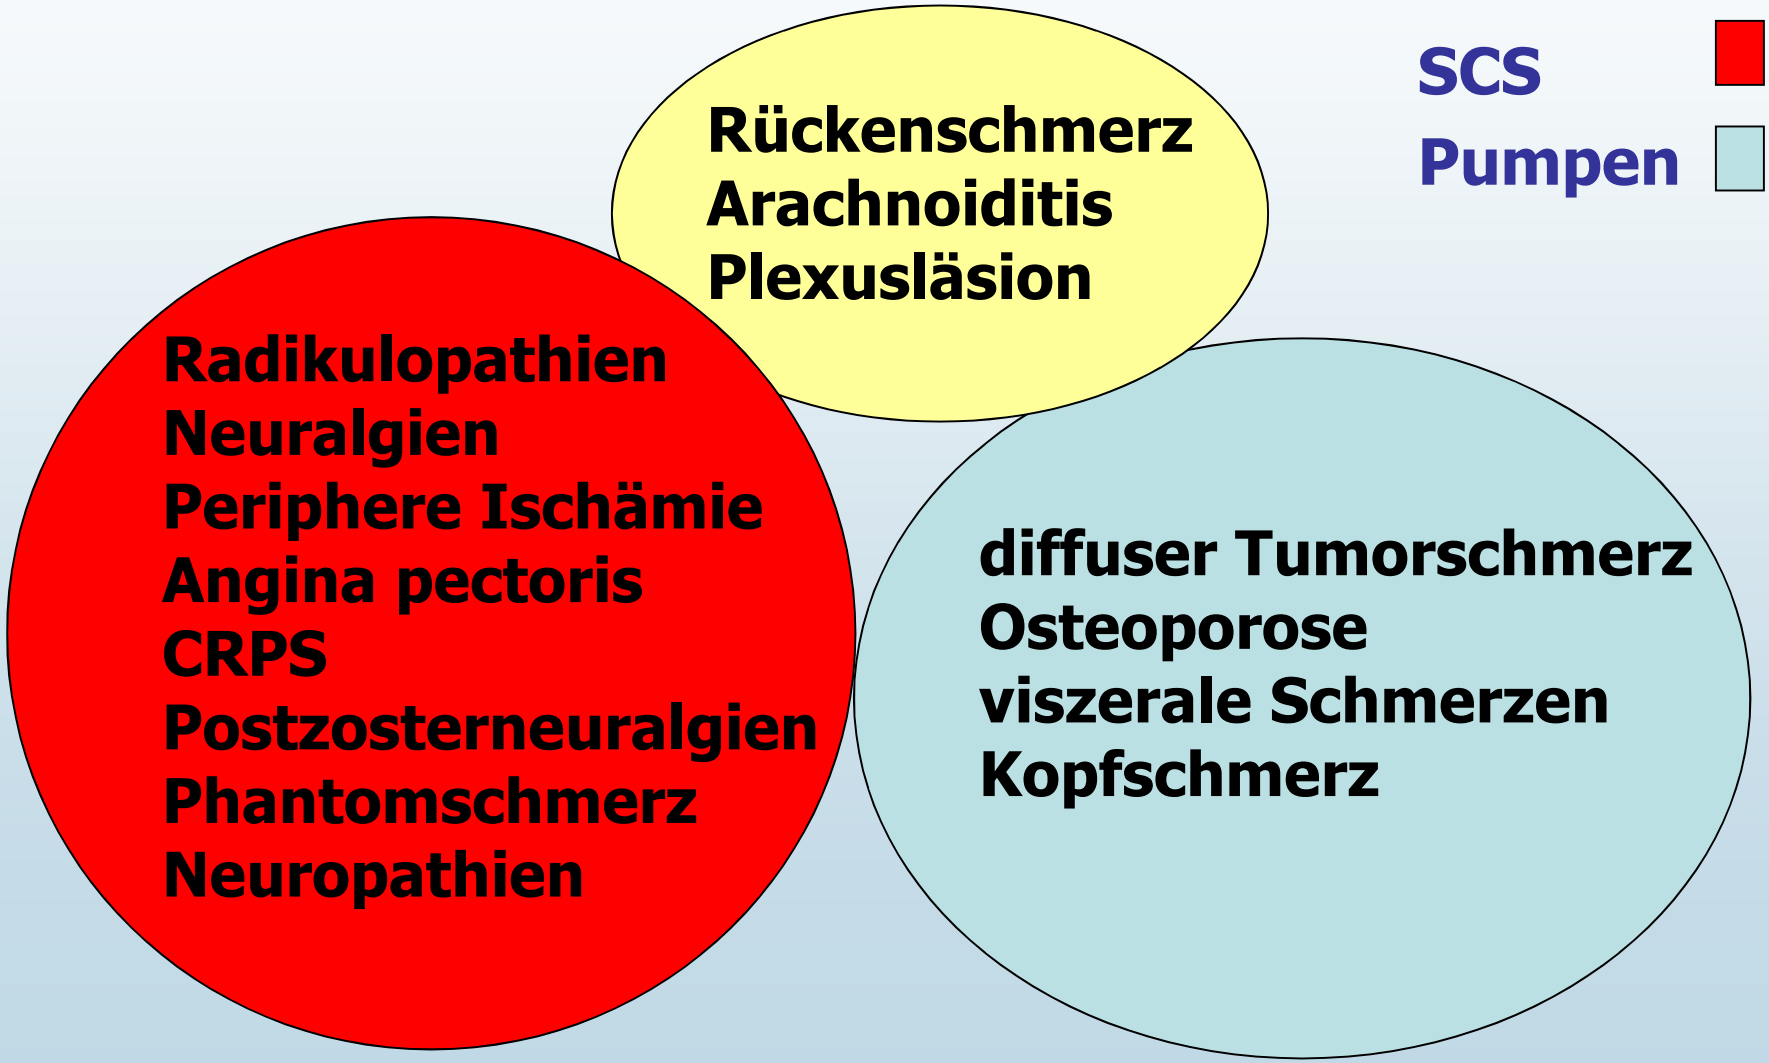
Indikationen für SCS



Absolute criteria for the consideration of SCS, selected by the expert panel

KABEG
KLINIKUM KLAGENFURT
AM WÖRTHERSEE

Inclusion criteria	Exclusion criteria

• Age ≥ 18 years
• Chronic pain with a duration of least 6 months
• One of the following primary indications:
  • Chronic low back/leg pain
  • Complex regional pain syndrome
  • Neuropathic pain syndrome
  • Ischaemic pain syndrome
• Pain severity at least moderate (VAS ≥ 5) having a substantial impact on daily functioning and quality of life
• Insufficiently responding to appropriate trials of medication and/or minimally invasive treatments (such as local anaesthetic nerve blocks) and/or experiencing intolerable side effects of these treatments
• No clear benefits of surgery expected
	• Unwilling to have an implant
	• Unable to manage the device
	• Absolute contra-indications for active treatment (e.g. unfit for undergoing SCS, pregnancy, spine infection, coagulation disorder)
	• Uncontrolled disruptive psychological or psychiatric disorder
	• Ongoing alcohol and drug misuse
	• Widespread pain

Table 2. Commercially Available Neurostimulators and Leads.

Company	Device	Device type	Target	Approvals
BioControl Medical	CardioFit	Responsive stimulation of right vagus nerve	Right vagus nerve	EU
Bioness	H200 Wireless	Noninvasive prosthesis for functional electrical stimulation	Arm flexor, extensor muscles	EU, US
Bioness	L300	Noninvasive prosthesis for functional electrical stimulation	Peroneal nerve, anterior tibialis	EU, US
Bioness	L300 Plus	Noninvasive prosthesis for functional electrical stimulation	Quadriceps or hamstring	US
Bioness	StimRouter	External pulse transmitter, implanted lead	Median nerve	Pending US
Boston Scientific	Artisan 2 × 8 Surgical Lead	Paddle lead with 16 electrodes	Spinal cord	AU, CA, EU, US
Boston Scientific	Infinion 16 Lead	Cylindrical lead with 16 electrodes	Spinal cord	AU, CA, EU, US
Boston Scientific	Linear 8 Contact Lead	Cylindrical lead with 8 electrodes; 6-, 4-, or 1-mm spacing	Spinal cord	AU, CA, EU, US
Boston Scientific	Precision Plus	Rechargeable, constant-current IPG	Spinal cord	AU, CA, EU, US
Boston Scientific	Precision Spectra	IPG	Spinal cord	EU
Boston Scientific	Vercise	IPG	Brain	AU, EU
Cerbomed	NEMOS	Transcutaneous vagus nerve stimulator	Vagus nerve	EU
CerebralRx	FitNeS	IPG	Left vagus nerve	EU
CVRx	Barostim Neo	IPG	Right carotid artery	EU
CVRx	Rheos	IPG	Carotid arteries	EU
Cyberonics	VNS Therapy Generators	IPG	Left vagus nerve	CA, EU, US
Cyberonics	VNS Therapy Leads	Leads	Left vagus nerve	CA, EU, US
EndoStim	EndoStim	IPG	Lower esophageal sphincter	EU
EnteroMedics	Maestro RC	Rechargeable high-frequency IPG	Vagus nerve	AU, EU
EnteroMedics	Maestro RC leads	Anterior and posterior leads	Vagus nerve	AU, EU
ImThera	aura6000	Rechargeable IPG	Hypoglossal nerve	EU
IntraPace	abiliti	IPG	Stomach	EU
Medtronic	1 × 4 Percutaneous Leads	Cylindrical lead with four electrodes; 12-, 6- or 4-mm spacing	Spinal cord	AU, CA, EU, US
Medtronic	1 × 8 Percutaneous Leads	Cylindrical lead with eight electrodes; 6-, 4- or 1.5-mm spacing	Spinal cord	AU, CA, EU, US
Medtronic	4-Electrode Surgical Leads	Paddle lead with four electrodes	Spinal cord	AU, CA, EU, US
Medtronic	8-Electrode Surgical Leads	Paddle lead with eight electrodes	Spinal cord	AU, CA, EU, US
Medtronic	16-Electrode Surgical Leads	Paddle lead with 16 electrodes	Spinal cord	AU, CA, EU, US
Medtronic	Activa PC	Dual-channel, nonrechargeable, constant-current/voltage IPG	Brain	AU, CA, EU, US
Medtronic	Activa RC	Dual-channel, rechargeable, constant-current/voltage IPG	Brain	AU, CA, EU, US
Medtronic	Activa SC	Single-channel, nonrechargeable, constant-current/voltage IPG	Brain	AU, CA, EU, US
Medtronic	DBS Lead 3387	Cylindrical lead with four electrodes, 1.5-mm spacing	Brain	AU, CA, EU, US
Medtronic	DBS Lead 3389	Cylindrical lead with four electrodes, 0.5 mm spacing	Brain	AU, CA, EU, US
Medtronic	Enterra	Nonrechargeable IPG	Stomach muscle	CA, EU, US
Medtronic	InterStim & InterStim II	Nonrechargeable IPG	Sacral nerve	AU, CA, EU, US
Medtronic	Itrel 4	Nonrechargeable constant-voltage IPG	Spinal cord	AU, CA, EU, US
Medtronic	PrimeAdvanced	Nonrechargeable constant-voltage IPG	Spinal cord	AU, CA, EU, US
Medtronic	RestoreAdvanced	Rechargeable constant-voltage IPG	Spinal cord	AU, CA, EU, US
Medtronic	RestorePrime	Nonrechargeable constant-voltage IPG	Spinal cord	AU, CA, EU, US
Medtronic	RestoreSensor	Rechargeable constant-voltage IPG	Spinal cord	AU, CA, EU, US
Medtronic	RestoreUltra	Rechargeable constant-voltage IPG	Spinal cord	AU, CA, EU, US
Medtronic	Tined Leads 3889 & 3093	Cylindrical lead with four electrodes; 1.5- or 3.0-mm spacing	Sacral nerve	AU, CA, EU, US
Medtronic	Unipolar Intramuscular Lead	10-mm electrode	Stomach muscle	CA, EU, US
NeuroPace	RNS System	Responsive neurostimulator	Cortex	US
Neurostream	Neurostep	IPG	Leg peripheral nerves	EU
Nevro	8-Contact Percutaneous Leads	Cylindrical lead with eight electrodes	Spinal cord	EU
Nevro	Senza HF-SCS	Rechargeable high-frequency IPG	Spinal cord	EU

Table 3. Alternative Methods of Current Delivery in Neurostimulation Devices.

Method	Device description	Potential advantages
High frequency	Neurostimulation devices that utilize higher pulse rates than conventional stimulators are being developed and tested for alleviating chronic pain (154,156). For example, one such device delivers pulses at a rate of 10,000 Hz to the spinal cord (155) and peripheral nerve neuromas (157). Due to the high pulse rate, this type of stimulation does not produce paresthesia.	-Patients do not experience paresthesia. -May produce greater pain reduction than conventional stimulation in the back.
Burst	Delivers stimulating pulses in bursts (158,159) of 5 spikes lasting 1 msec each (with a 1 msec interspike interval) 40 times per second. This pattern of stimulation does not produce paresthesia.	-Patients do not experience paresthesia. -May salvage patients who have failed conventional SCS.
Microwave powered	Microwave neurostimulation device consists of a 1 cm long dipole platinum wire antenna and Schottky diode contained within 0.8 mm diameter polyimide tubing (160). Both ends of the tubing terminate in 1 mm platinum balls that function as stimulating electrodes. Current delivery must be limited to levels of microwave radiation that can be safely absorbed.	-Will eliminate the need for an IPG -The microwave transmitter can be up to 7 cm from body surface, providing wireless stimulation. -May be ideal for PNS and PNfS
Waveforms	Alternative waveforms have been developed for neurostimulation devices such as deep brain stimulation devices (161). For example, replacing standard rectangular waveforms (mono- or biphasic) with alternative waveforms (e.g., triangular or Gaussian or "randomly modulated" or mimicking normal neural activity from the target; i.e., other novel waveforms) may produce positive effects and even be energy saving.	-More energy efficient waveforms have the potential to increase neurostimulator device lifetime, reducing or delaying the need for additional surgeries.
Closed loop	Involves neural sensors and stimulating electrodes. The sensors provide data to adjust stimulation parameters dynamically, for example, localizing stimulation in the epileptogenic brain region during an epileptic seizure (162).	-Faster adjustments in stimulation than manual patient adjustment -May alleviate the need for accelerometers and similar sensors
Sensing	SCS device that detects changes in body position (163). The patient's desired stimulation levels in a position are programmed into the stimulator and that setting is automatically applied as body position changes.	-Automatic adjustments may result in better satisfaction. -Fewer manual adjustments in stimulation are required by patients.

IPG, implantable pulse generator; PNfS, peripheral nerve field stimulation; PNS, peripheral nerve stimulation.

Deer TR, Krames E, Mekhail N. et al.The Appropriate Use of Neurostimulation: New and Evolving Neurostimulation Therapies and Applicable Treatment for Chronic Pain andSelected Disease States. Neuromodulation 2014; 17: 599–615

Table 1. Hierarchy of Studies by the Type of Design (U.S. Preventive Services Task Force, Ref [7]).

Evidence level	Study type
I	At least one controlled and randomized clinical trial, properly designed
II-1	Well-designed, controlled, nonrandomized clinical trials
II-2	Cohort or case studies and well designed-controls, preferably multicenter
II-3	Multiple series compared over time, with or without intervention, and surprising results in noncontrolled experiences
III	Clinical experience-based opinions, descriptive studies, clinical observations or reports of expert committees.

Table 2. Meaning of Recommendation Degrees (U.S. Preventive Services Task Force, Ref [7]).

Degree of recommendation	Meaning
A	Highly recommended (good evidence that the measure is effective and benefits outweigh the harms)
B	Recommended (at least, moderate evidence that the measure is effective and benefits exceed harms)
C	Neither recommend nor advise (at least moderate evidence that the measure is effective, but benefits are similar to harms and a general recommendation cannot be justified)
D	Not advisable (at least moderate evidence that the measure is ineffective or that the harms exceed the benefits)
I	Insufficient, low quality, or contradictory evidence; the balance between benefit and harms cannot be determined.

Deer et al., The Polyanalgesic Consensus Conference (PACC): Recommendations for Intrathecal Drug Delivery: Guidance for Improving Safety and Mitigating Risks, International Neuromodulation Society, 2017, 20:155-176.

Table 3. Strength of Consensus.

Strength of consensus	Definition*
Strong	>80% consensus
Moderate	50–79% consensus
Weak	<50% consensus

*Quorum defined as 80% of participants available for vote.

Deer et al., The Polyanalgesic Consensus Conference (PACC): Recommendations for Intrathecal Drug Delivery: Guidance for Improving Safety and Mitigating Risks, International Neuromodulation Society, 2017, 20:155-176.

Table 1. Classification of the Quality of Evidence, Strength of Recommendation, and Description of the Recommendation

Quality of Evidence	Strength of Recommendation	Recommendation
High	Strong	Must (not) be used
Moderate	Moderate	Should (not) be used
Low	Weak	Could (not) be used
Very low	Very weak	Could (not) be considered

Tab. 1	Empfehlungen der Leitlinie	
CRPS I	A	Bleiben alle Versuche einer multimodalen konservativen Therapie des CRPS I ohne dauerhaften Erfolg, sollte eine Therapie mit epiduraler Rückenmarkstimulation unter Beibehaltung einer intensiven physikalischen Behandlung angeboten werden.
CRPS II	O	Ein individueller Behandlungsversuch kann bei CRPS II bei Wirkungslosigkeit konservativer Maßnahmen erwogen werden.
FBSS	B	Die SCS sollte beim FBSS mit prädominantem neuropathischem Beinschmerz bei Erfolglosigkeit konservativer Verfahren und Ausschluss psychologischer Kontraindikationen eingesetzt werden.
FBSS	O	Ein individueller Behandlungsversuch kann bei überwiegendem Kreuzschmerz bei Wirkungslosigkeit konservativer Maßnahmen erwogen werden.
Angina pectoris	A	SCS soll bei refraktärer Angina pectoris bei KHK nach Ausschöpfung aller konservativen und interventiven Therapiemaßnahmen eingesetzt werden.
PAVK	A	SCS soll bei pAVK Stadium IIb–III nach erfolgloser konservativer, interventiver Therapie eingesetzt werden.
PAVK	O	Ein Behandlungsversuch kann bei anderen vasokonstriktorischen Erkrankungen wie Morbus Raynaud, Thrombangiitis obliterans nach erfolgloser konservativer Therapie erwogen werden.

Table 1 Summary of GRADE results in neurostimulation studies of neuropathic pain, CRPS I and fibromyalgia

Procedure	Neuropathic pain				Complex regional pain syndrome type I				Fibromyalgia			
Assessment	Final quality of evidence	Effect size	Tolerability/ safety	Values and preferences	Final quality of evidence	Effect size	Tolerability/safety	Values and preferences	Final quality of evidence	Effect size	Tolerability/ safety	Values and preferences
SCS[a]	Low	Low	Moderate	ND	Low	Low	Moderate	ND				
DBS	Very low	Very low	Moderate	ND								
MCS	Very low	Low	Moderate	High[b]								
rTMS of M1	Low	Low	High	ND	Very low	Low	High	ND	Low	Low	High	ND
rTMS of DLPFC	Very low	Low	High	ND					Very low	Low	High	ND
tDCS of M1	Low	Low	High	ND					Low	Low	High	ND
tDCS of DLPFC	Very low	Low	High	ND					Very low	Low	High	ND

CRPS I, complex regional pain syndrome type I; DBS, deep brain stimulation; DLPFC, dorsolateral prefrontal cortex; M1, primary motor cortex; MCS, epidural motor cortex stimulation; ND, not determined; rTMS, repetitive transcranial magnetic stimulation; SCS, spinal cord stimulation; tDCS, transcranial direct current stimulation.

[a]SCS is the only procedure that was studied specifically in post-surgical chronic back and leg pain (two randomized controlled studies): final quality of evidence was low, effect size was moderate, tolerability/safety was moderate and patients' preferences compared to reoperation or standard of care were high; [b]in one study, a number of patients with insignificant pain relief were willing to be reoperated for the same outcome [14].

Table 2 Summary of GRADE recommendations for neurostimulation in chronic pain

Procedure	Neuropathic pain	Post-surgical chronic back and leg pain	CRPS I	Fibromyalgia
Spinal cord stimulation				
SCS versus conventional management	Weak for	Weak for	Weak for	
SCS versus reoperation		Weak for		
Deep brain stimulation	Inconclusive			
Epidural motor cortex stimulation	Weak for			
Repetitive transcranial magnetic stimulation				
rTMS of M1	Weak for		Inconclusive	Weak for
rTMS of DLPFC	Inconclusive			Inconclusive
Transcranial direct current stimulation				
tDCS of M1	Weak for (inconclusive in SCI)			Inconclusive
tDCS of DLPFC	Inconclusive			Inconclusive

CRPS I, complex regional pain syndrome type I; DLPFC, dorsolateral prefrontal cortex; M1, primary motor cortex; rTMS, repetitive transcranial magnetic stimulation; SCI, spinal cord injury; SCS, spinal cord stimulation; tDCS, transcranial direct current stimulation.

Cruccu G, Garcia-Larrea L; Hansson P et al.EAN guidelines on central neurostimulation therapy in chronic painconditions. European Journal ofNeurology 2016, 23: 1489–1499

Bleiben alle Versuche einer multimodalen konservativen Therapie des CRPS I ohne dauerhaften Erfolg, sollte eine Therapie mit epiduraler Rückenmarkstimulation unter Beibehaltung einer intensiven physikalischen Behandlung angeboten werden.

Kemler MA, Barends GA, Kleef M van et al (2000) Spinal cord stimulation in patients with chronic reflex sympathetic dystrophy. N Engl J Med 343:618-643

Tronnier V. et al Epidurale Rückenmarkstimulation zur Therapie chronischer Schmerzen S3 Leitlinie Der Schmerz 2012

Die SCS sollte beim FBSS mit prädominantem neuropathischem Beinschmerz bei Erfolglosigkeit konservativer Verfahren und Ausschluss psychologischer Kontraindikationen eingesetzt werden.

Kumar K, Taylor RS, Jacques L et al (2007) Spinal cord stimulation versus conventional medical management for neuropathic pan: A multicentre randomised controlled trial in patients with failed back surgery syndrome. Pain 132:179-188

Taylor RJ, Taylor RS (2005) Spinal Cord stimulation for failed back surgery syndrome: a decision analytic model and cost-effectiveness analysis. Int J Technol Assess Health 21:351-358

Ein individueller Behandlungsversuch kann bei überwiegendem Kreuzschmerz bei Wirkungslosigkeit konservativer Maßnahmen erwogen werden.

Taylor RS (2006) Spinal cord stimulation in complex regional pain syndrome and refractory neuropathic back and leg pain/failed back surgery syndrome: results of a systematic review and metaanalysis. J Pain Symptom Manage 32:S13-S19

Turner JA, Loeser JD, Bell KG (1995) Spinal cord stimulation for chronic low back pain: a sytematic literature review synthesis. Neurosurgery 37:1088-1096

Die SCS ist bei therapierefraktärer Angina pectoris effektiv und senkt die kardiovaskuläre Morbidität, die Häufigkeit und Intensität der Anginaattacken; sie reduziert den Nitratverbrauch und die Häufigkeit Angina-bedingter Krankenhausaufenthalte. SCS soll bei refraktärer Angina pectoris bei KHK nach Ausschöpfung aller konservativen und interventiven Therapiemaßnahmen eingesetzt werden.

Andrell P, Ekre O, Eliasson T et al (2003) Cost-effectiveness of spinal cord stimulation versus coronary artery bypass grafting in patients with severe angina pectoris – long-term results from the ESBY study. Cardiology 99:20-24

Die SCS ist bei peripherer arterieller Verschlusskrankheit über einen Zeitraum von 12 Monaten effektiv und kann zu einem Erhalt der betroffenen Extremitäten beitragen. SCS soll bei pAVK Stadium IIb-III nach erfolgloser konservativer, interventiver Therapie eingesetzt werden.

Donas KP, Schulte S, Ktenidis K et al (2005) The role of epidural spinal cord stimulation in the treatment of Buerger's disease. J Vasc Surg 41:830-836

Pace AV, Saratzis N, Karokis D et al (2002) Spinal cord stimulation in Buerger's disease. Ann Rheum Dis 61:1114

Bei anderen vasokonstriktorischen Erkrankungen wie Morbus Raynaud oder Thrombangiitis obliterans liegen positive Fallberichte vor. Ein Behandlungsversuch kann bei anderen vasokonstriktorischen Erkrankungen wie Morbus Raynaud, Thrombangiitis obliterans nach erfolgloser konservativer Therapie erwogen werden.

Donas KP, Schulte S, Ktenidis K et al (2005) The role of epidural spinal cord stimulation in the treatment of Buerger's disease. J Vasc Surg 41:830-836

Pace AV, Saratzis N, Karokis D et al (2002) Spinal cord stimulation in Buerger's disease. Ann Rheum Dis 61:1114

Bei chronischen Schmerzen durch Nervenverletzungen oder Gefäßleiden steht die epidurale Rückenmarkstimulation für medikamentös nicht ausreichend therapierbare Fälle zur Verfügung. Vor der Überweisung solcher Patienten an Schmerztherapiezentren sollte die Indikation genau überprüft werden. Weniger invasive medikamentöse und physikalische Maßnahmen sollten ausgeschöpft sein oder wegen intolerabler Nebenwirkungen nicht in Betracht kommen. Die Patienten müssen informiert sein, dass die epidurale Rückenmarkstimulation Teil eines Gesamtschmerztherapiekonzepts ist.

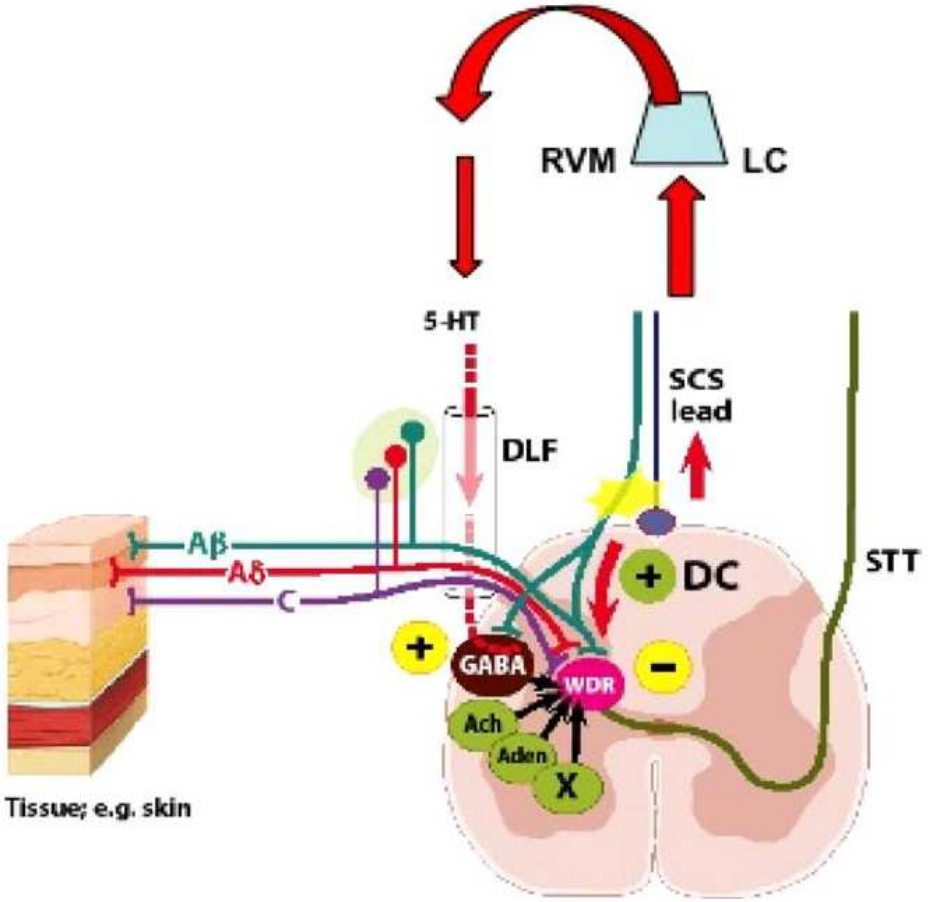

Figure 1. Schematic summary of the known segmental and supraspinal mechanisms involved in conventional SCS when applied for neuropathic pain. Antidromic stimulation of DC afferents induces activation of inhibitory interneurons in the dorsal horns and the ortodromic impulses in the DCs activate neurons in the RVM and the locus coeruleus (LC) in the brainstem, leading to descending inhibition further strengthening the segmental inhibitory mechanisms (adapted from Linderoth and Meyerson, Anesthesiology 2010 (38)).

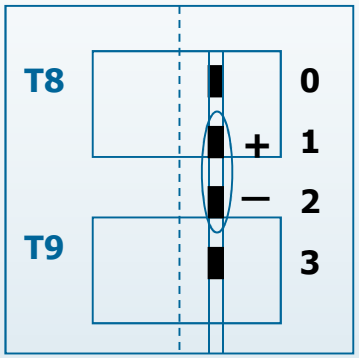
Linderoth et al., Conventional and Novel Spinal Stimulation Algorithms: Hypothetical Mechanisms of Action and Comments on Outcomes. Neurostimulation. 2017.

PARAMETERWAHL

Zentraler Bipol

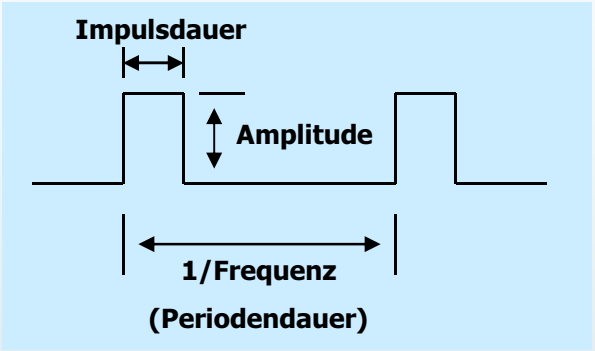


Erhöhung der Effizienz oft noch durch sog. „Guarded Cathode"

1 +

2 –

3 +



Parameter	empf. Anfangswert	Bereich	Werte aus der Praxis	Effekt der Anpassung
Pulsbreite	210 µs	60 - 450 µs	60 - 450 µs	Änderung der relativen Ausdehnung
Frequenz	50 Hz	2,1 - 130 Hz	35 - 50 Hz	Änderung der Art der Parästhesien
Amplitude	0 V	0 - 10,5 V	1,0 - 8,0 V	Stärke der Parästhesien

Vorsicht: Vor Erhöhung von Impulsdauer oder Frequenz auf jeden Fall Amplitude reduzieren, da es sonst durch überhöhte „Energiezufuhr" für den Patienten zu einer schmerzhaften Stimulation führen kann !

Current SCS Options

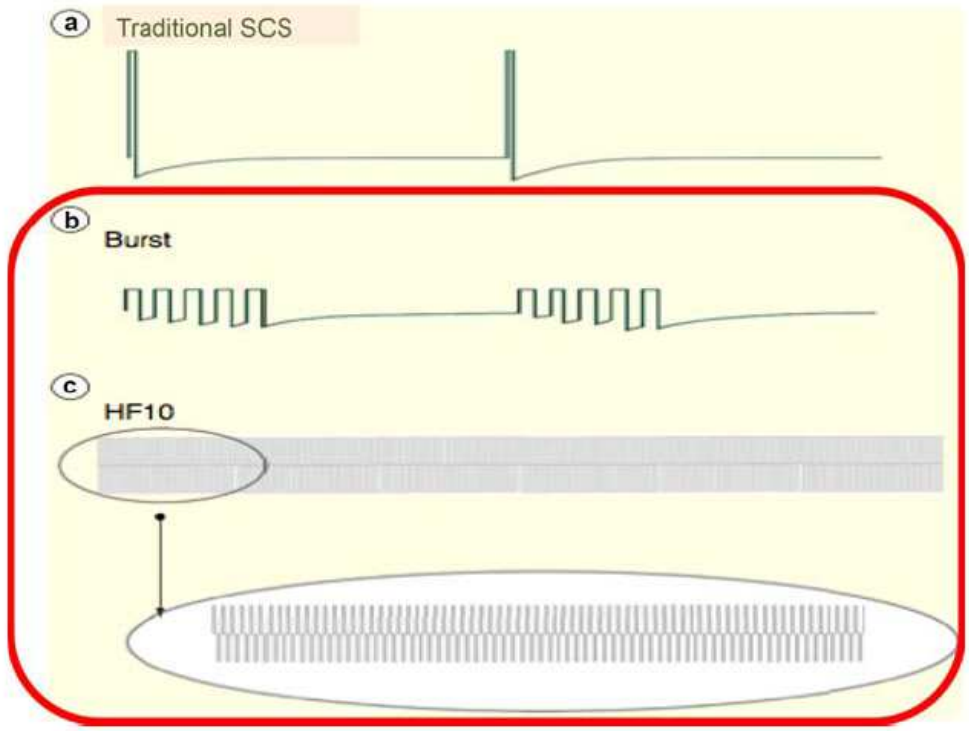

Figure 2. Current SCS options: the new algoritms are framed by a red rectangle. a. Conventional SCS freq. about 30–80 Hz; b. Burst SCS with internal pulse freq. 500 Hz and burst repetition rate 40 Hz; c. High frequency stimulation—usually 10 kHz (adapted from Pope, Falowski, and Deer 2015 (49)).

Linderoth et al., Conventional and Novel Spinal Stimulation Algorithms: Hypothetical Mechanisms of Action and Comments on Outcomes. Neurostimulation. 2017.

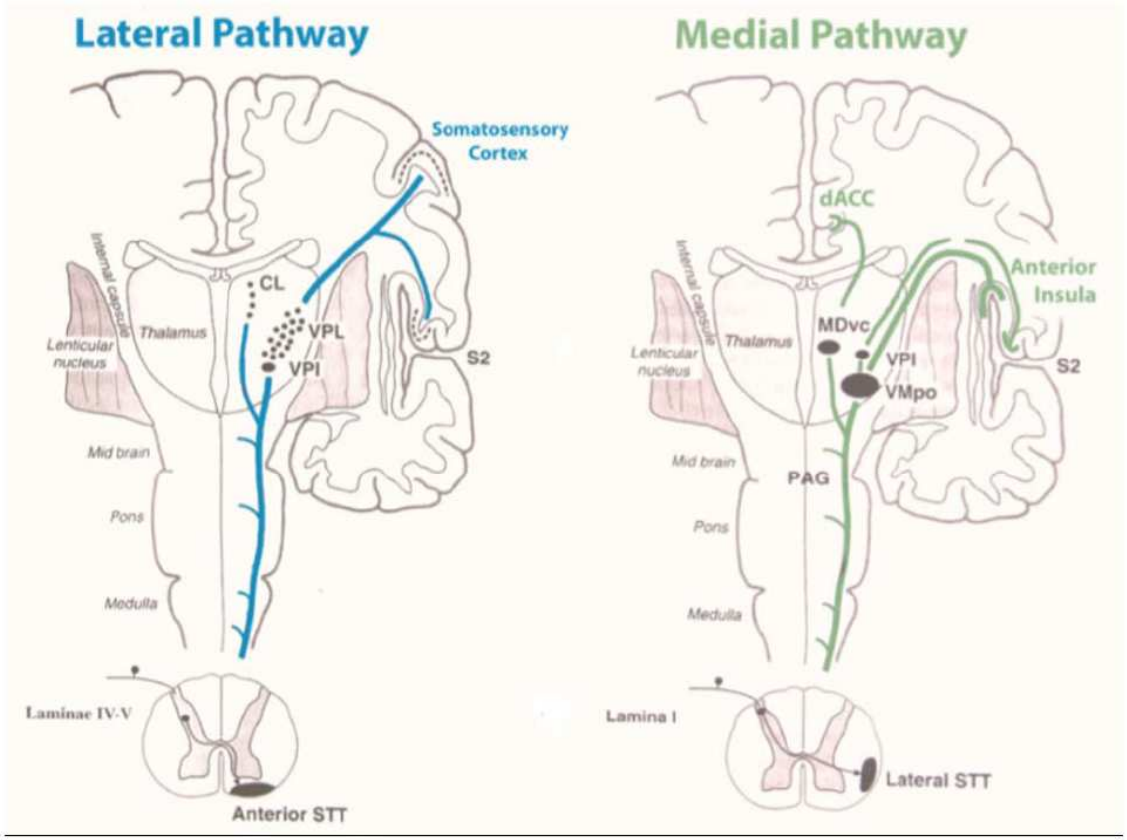

Figure 3. Present "working hypotheses" for mechanisms behind effects of burst stimulation of the spinal cord (adapted from De Ridder and Vanneste 2015 (76)). Burst SCS is hypothesized to especially modulate the activation of the medial (affective/attentional) pathway (on the right in the figure).

Linderoth et al., Conventional and Novel Spinal Stimulation Algorithms: Hypothetical Mechanisms of Action and Comments on Outcomes. Neurostimulation. 2017.

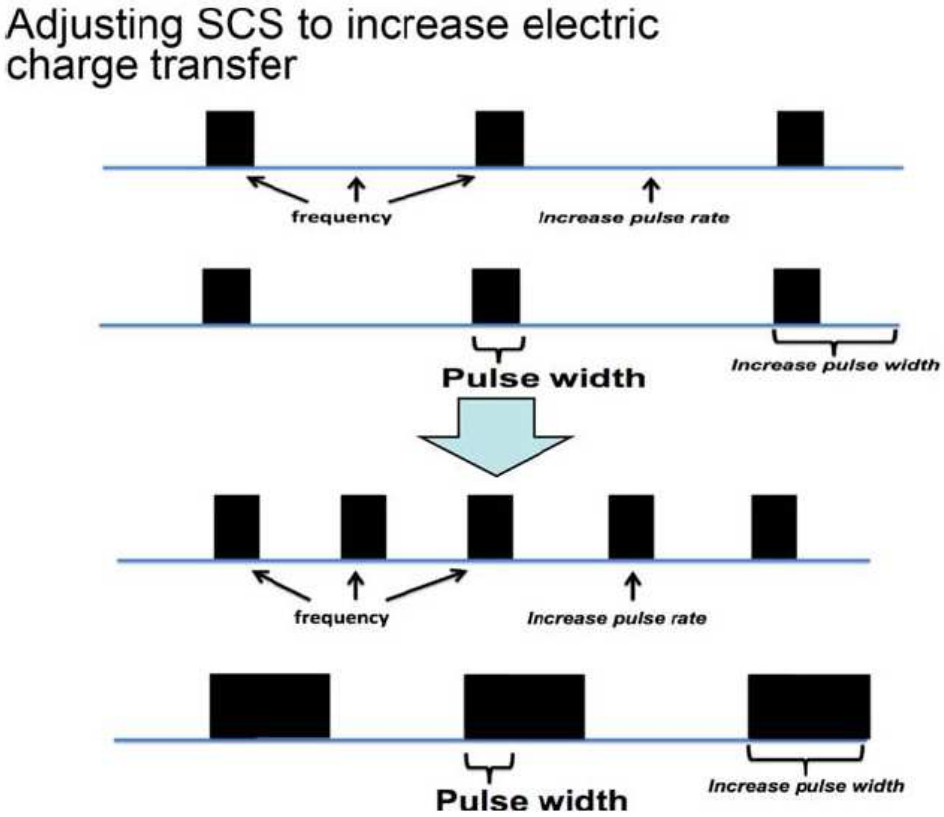

Figure 4. Illustrates how merely increasing stimulation frequency and/or pulse duration can increase the amount or electric charge transmitted. [Color figure can be viewed at wileyonlinelibrary.com]

Linderoth et al., Conventional and Novel Spinal Stimulation Algorithms: Hypothetical Mechanisms of Action and Comments on Outcomes. Neurostimulation. 2017.

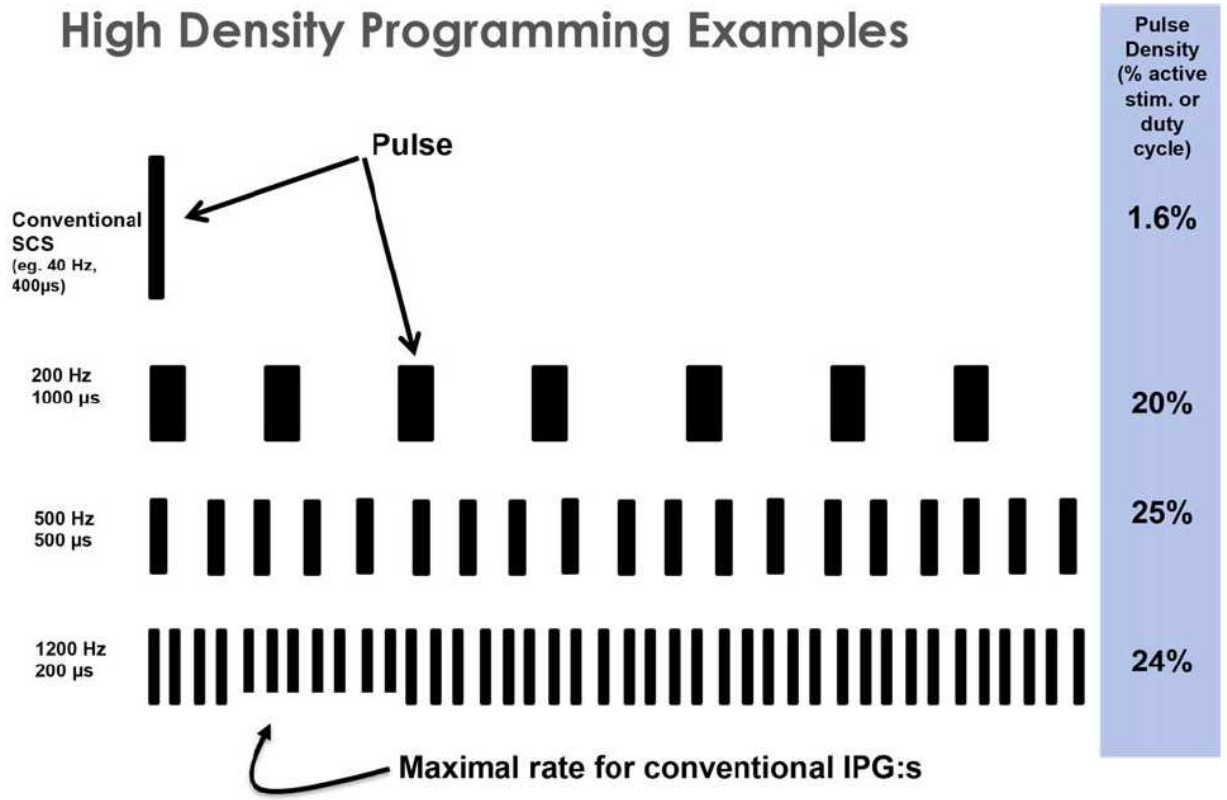

Figure 5. The figure illustrates how increases of the stimulation frequency result in higher pulse densities. It is evident that the conventional SCS settings produce a low pulse density while the lower parts of the picture with settings of 500 Hz/500 μsec or 1200 Hz and 200 μsec can produce pulse densities between 24 and 25% even with subparestetic amplitudes. IPG, Implantable Pulse Generator. [Color figure can be viewed at wileyonlinelibrary.com]

Stimulationsmöglichkeiten

- **Spinal Cord Stimulation (SCS)**
- **Dorsal Root Stimulation (DRS)**
- **Periphere Nervenstimulation (PNS)**
- **Subkutane Nervenstimulation (s.c.NS)**
- **Motorcortex Stimulation**

Stimulation options

- **Spinal Cord Stimulation (SCS)**

  HF –Stimulation – Adaptive Stimulation - High Density Stimulation

- **Nerve Root Stimulation (NRS)**

  Dorsal Root ganglion stimulation

- **Peripheral Nerve Stimulation (PNS)**

- **Subcutaneous Peripheral (Nerve)Field Stimulation (s.c.NS)**

- **Motor Cortex Stimulation**

Recommendations of the PACC to reduce morbidity and mortality

1. **The use of IDDS** (intrathecal drug delivery systems) to treat chronic pain **should be part of a treatment algorithm** that involves the failure of more conservative attempts at treatment. IDDS should be considered prior to other options when unacceptable side-effects or lack of efficacy is established.

2. **The use of IDDS should be based on** an analysis of safety, efficacy, a goal of economic neutrality and appropriateness for **the individual patient**. These factors have been described as the S.A.F.E. principles.(safety,approppriateness,fiscal neutrality,efficacy)

3. Spinal cord stimulation (SCS), peripheral nerve stimulation (PNS), and hybrids of both SCS and PNS should be considered inappropriate candidates prior to considering an IDDS.

4. Psychological evaluation and stability should be confirmed prior to proceeding with an IDDS in noncancer patients.

Indikationsstellung zur neurostimulativen Therapie

- **chronischer Schmerz**
- **unzureichende Schmerzreduktion nach Ausschöpfung konservativer Therapieformen (erfahrenen Schmerztherapeuten)**
- **Ausschluss von somatoformen Schmerzsyndromen (Evaluation durch erfahrenen Psychologen/Psychiater)**
- **Compliance des Patienten**
- **endgültige Indikationsstellung in spezialisierten Zentren**
- **Ausschluss von Kontraindikationen**

Kontraindikationen für Neurostimulation

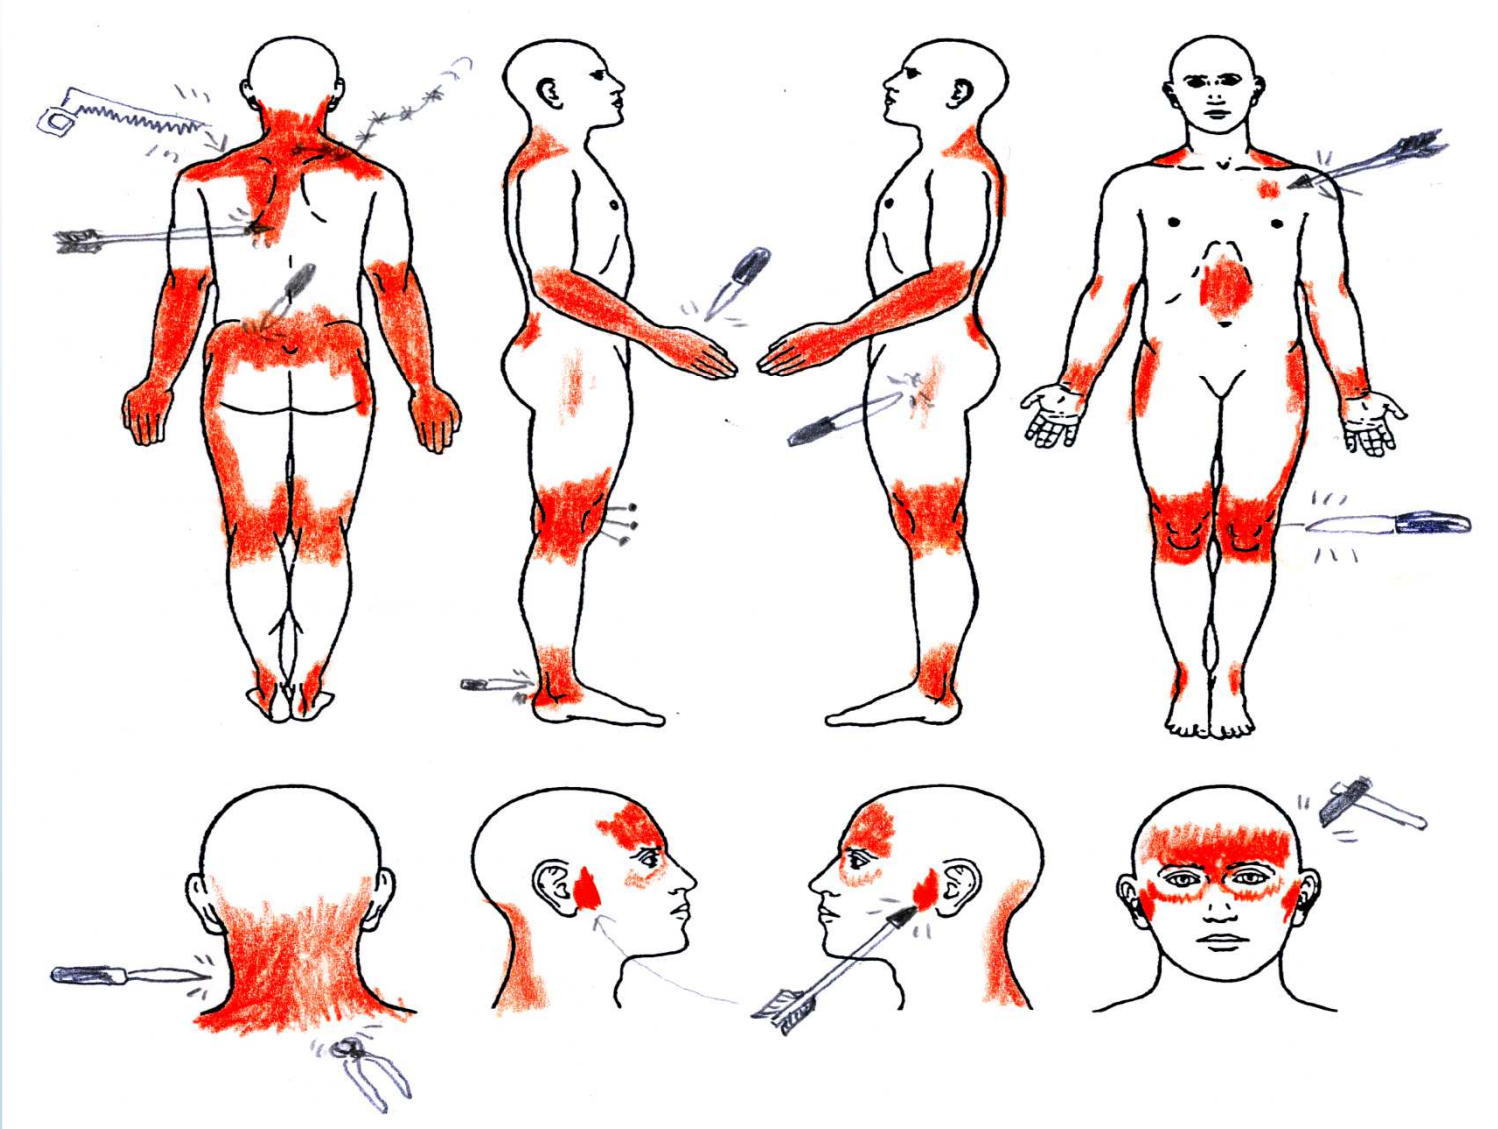
- **somatoforme Schmerzen**
- **Psychose**
- **endogene Depression**
- **mangelnde Compliance, Verständnis**

Alkohol- und Drogenabusus sind keine Kontraindikation

Kontraindikation für SCS

- **Komplexe Rückenmarksdurchtrennung**
- **Nervenwurzelausriss**
- **nozizeptiver Schmerz**

Krames, Neuromodulation 2004, 7: 82 - 88



- **Beim Failed back Surgery gibt es Einfluss von Alter.**
- **Bei Patienten über 50 ist der Erfolg größer.**
- **Je früher der Behandlungsbeginn desto besser der Therapieerfolg.**

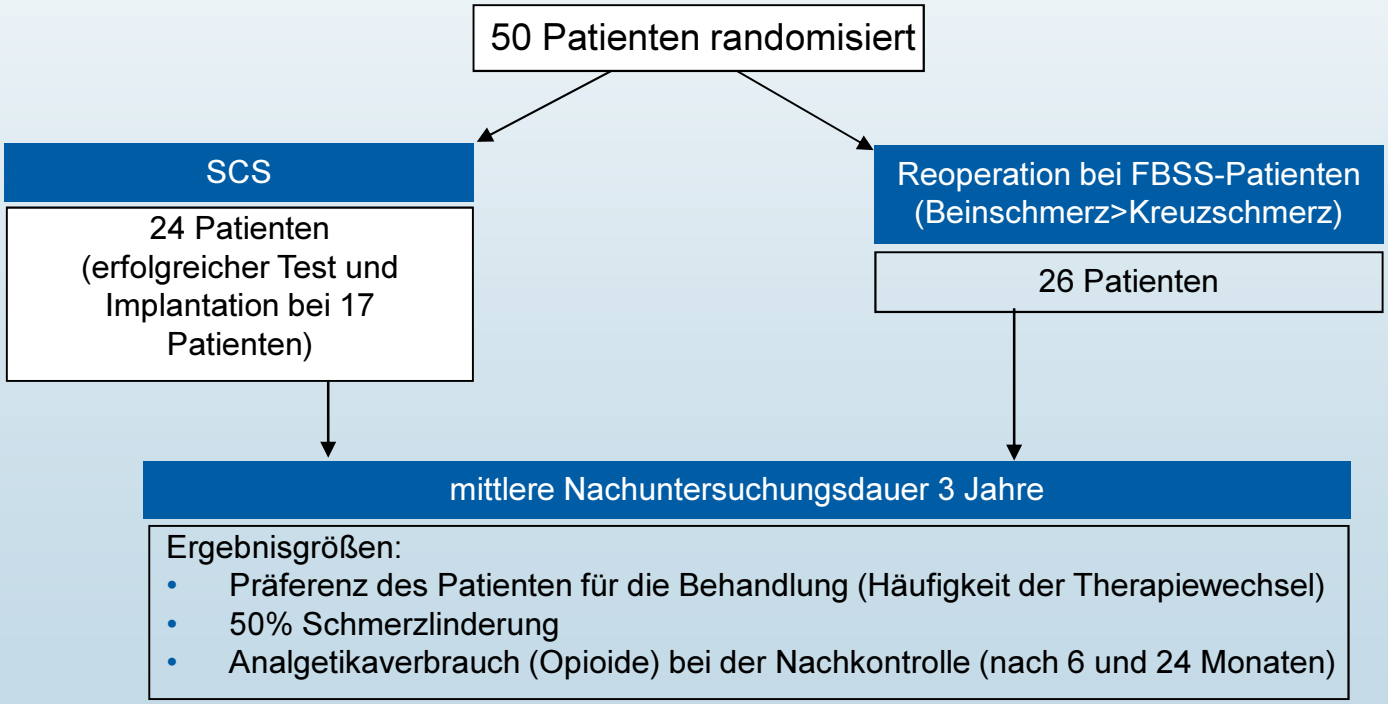
RCT: SCS vs. Reoperation bei FBSS-Patienten

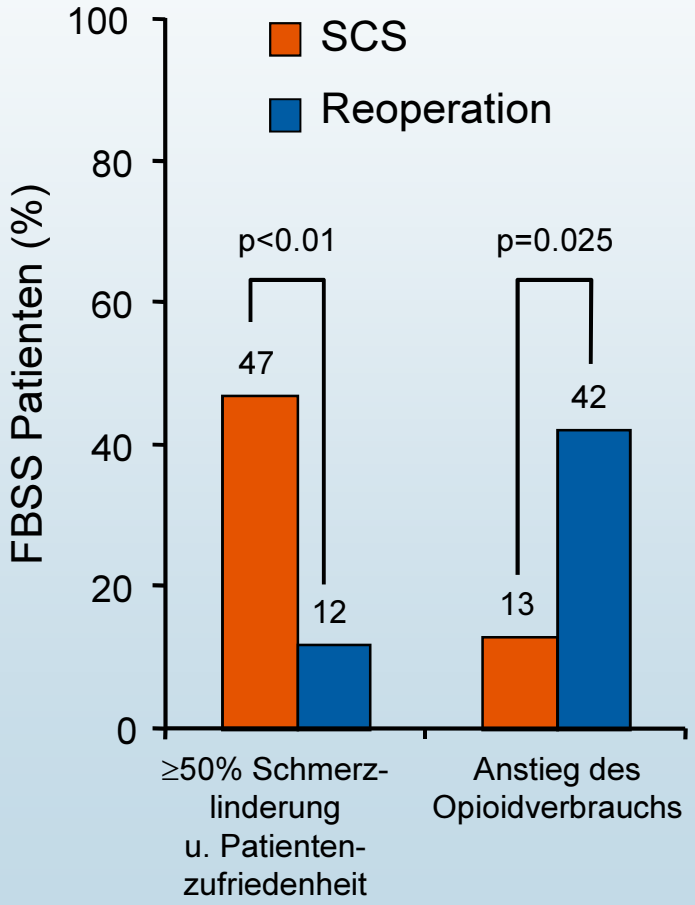
- **prospektive, kontrolliert randomisierte Studie[1]**
  - erhielt 4 von 5 Punkten auf der Jadad-Skala für methodische Qualität[2]



Evidenz der SCS bei schmerzhafter Radikulopathie

North et al. Neurosurg 2005
Jadad et al. Controlled Clin Trials 1996

SCS erfolgreicher als Reoperation bei FBSS – Ergebnisse einer 3-Jahres-RCT



RCT von North *et al.* ergab:

- **verbesserte Schmerzlinderung**
  - SCS wirksamer als Reoperation (p<0,01)
- **geringerer Anstieg der Opioiddosen**
  - Dosisreduktion bei SCS stärker als bei Reoperation (p=0,025)

North et al. Neurosurg 2005

SCS erfolgreicher als Reoperation bei FBSS – Ergebnisse einer RCT

Die RCT von North *et al*. hat ergeben:

- **SCS wurde von den Patienten bevorzugt**
  - die Rate der Therapiewechsel von Reoperation zu SCS war durchgehend höher als die Rate der Therapiewechsel von SCS zu Reoperation
    - 54% der Reoperationspatienten entschieden sich für einen Therapiewechsel zu SCS
    - nur 21% der SCS-Patienten entschieden sich für einen Therapiewechsel zur Reoperation

North et al. Neurosurg 2005

Austestung - Implantation

- **Stationäre Aufnahme**
- **Epidurale Platzierung der Sonden durch Anästhesist bzw. Neurochirurg, Patient nicht in Narkose**
- **Parästhesieausbreitung muss genau angegeben werden können.**
- **Probephase ca. 7 bis 14 Tage mit externem Stimulator.**
- **Fiximplantation in Allgemeinnarkose.**

Test-Stimulation	Erfolg
Bei richtiger Indikation	mehr als 70 %
Bei Angina pectoris	über 90 %
Bei peripheren Durchblutungsstörungen	79 %
Failed back Surgery	60 %
Komplex regionales Schmerzsyndrom	72 %

50 % Schmerzlinderung ist der goldene Standard
30 % ist klinisch relevant

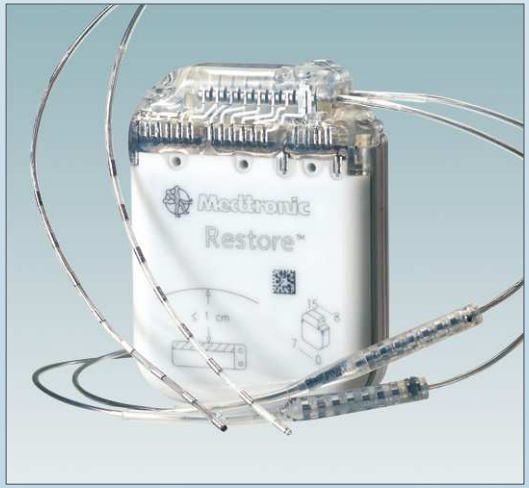
Technik Neurostimulation

Teststimulation - Screening Kabel

- **Multi-Channel Design**
  - **ein od. zwei 4-polige Elektroden**
  - **ein od. zwei 8-polige Elektroden**

Das Restore™-System

- **Wiederaufladbar**
- **Zum Anschluss von zwei 8-poligen Elektroden**
- **wesentlich kleiner als Synergy (39cc vs. 51cc)**
- **32 verschiedene Programme**
- **Lebensdauer: 9 Jahre**
- **Ladezyklen: 6 Tage bis 3 Monate**
- **Ladezeiten: 2 bis 6 Stunden**



Höhe der Elektroden:

- **Hals C2/C3**
- **Schulter C4**
- **Arm, Hand, Finger C4-C5**
- **LWS-Bereich , Gesäß Th9 – Th10**
- **Beine Th10-Th11**
- **Füße Th12**
- **ilioinguinal + genitofermoralis Versorgungsgebiet L3/L4 Punktion**

  Sonde lateral L1/L2

Höhe der Elektroden:

- **perinealer Schmerz**
  - → **sacrale Nervenwurzel**
- **Knieschmerz**
  - → **L3/L4 Nervenwurzel**
- **Fußschmerz**
  - → **L5/S1 Nervenwurzel L5 – Fußrücken, Fußsohle S1**
- **Coccygodynie**
  - → **Eingang L2/L3 (retrograd) oder Hiatus sacralis**
  - **S4 Bereich – Sonde**

ELEKTRODENLAGE

Die optimale Elektrodenposition ist abhängig vom Schmerzareal.

Rostrokaudale Position:

- **Nicht höher als Th 8 schieben**
- **(Dead Zone ⟷ breiter Liquorraum)**
- **Für Kreuz in aller Regel Th 8 bis Th 10 !**
- **Nur die Unterschenkel: Th 11 bis Th 12**

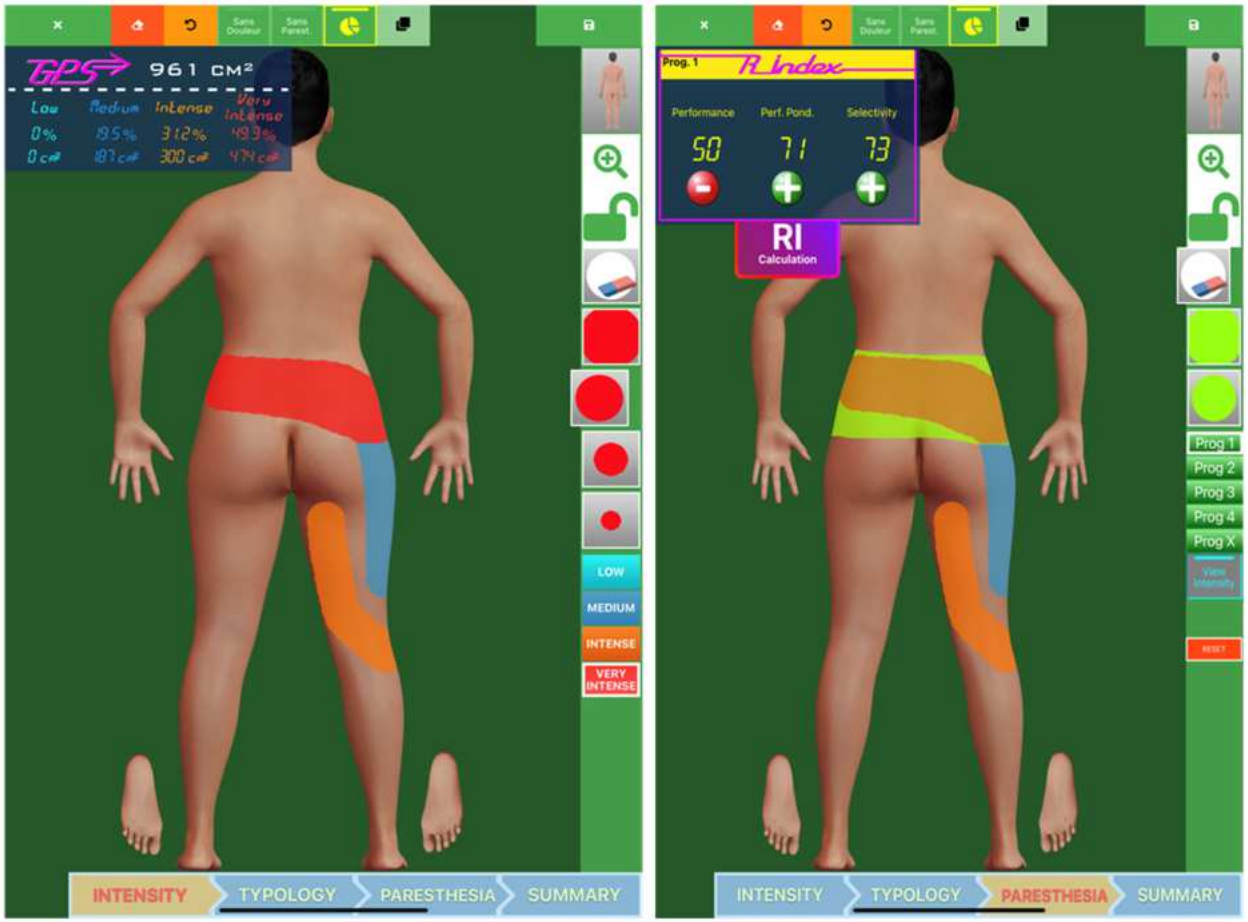
Dorsolaterale Position:

- **Für beide Beine (ohne Kreuzschmerzkomponenten !) recht theoretisch eine mediale Elektrode – allerdings mit der Gefahr der leichten Dislokation aus der Mitte und somit Verlust adäquater Schmerzlinderung.**

- **Konsequenz: Mit 2 Elektroden erzielt man generell maximale Flexibilität.**

- **Um zusätzlich zur radikulären Schmerzkomponente auch den Kreuzschmerz zu behandeln, unbedingt (möglichst !) laterale Positionierung der Elektrode(n).**

- **Konsequenz: Bei Kreuzschmerz unbedingt 2 Elektroden verwenden!**

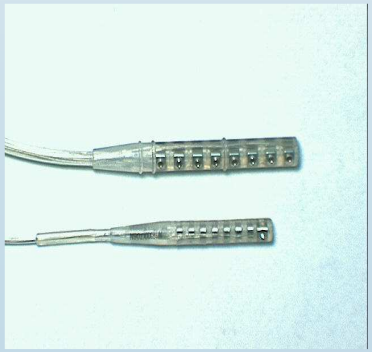


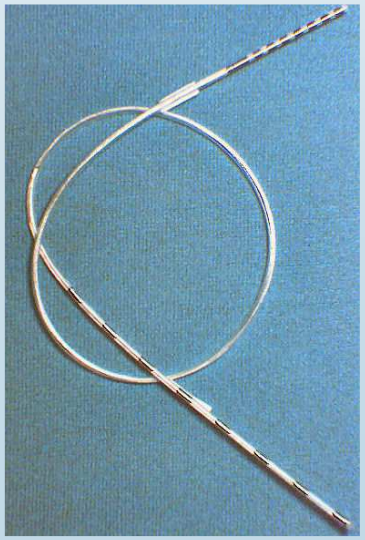
Pain mapping software used to assess pain surface and pain coverage where the patient could draw different painful zones. The pixels in the patient drawing are then converted into cm2, using several anatomical landmarks, patient morphology and morphometry. Four colors are available for patients to represent the different pain intensities. Pain coverage can then be obtained by drawing paresthesia (in green), which is converted to a percentage of pain coverage (performance).

Rigoard P., Ounajim A., Goudman L., et al. The Challenge of Converting „Failed Spinal Cord Stimulation Syndrome“ Back to Clinical Success, Using SCS Reprogramming as Salvage Therapy, through Neurostimulation Adapters Combined with 3D-Computerized Pain Mapping Assessment: A Real Life Retrospective Study. J Clin. Med. 2022, 11, 272.

Elektroden und Verlängerung

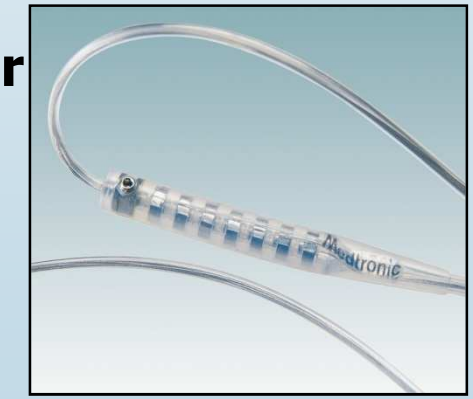
- **8-polige Elektroden**
  - **Impedanz <= 15 Ohm**
  - **Modelle: Sandard (3/6mm), Compact(3/4mm), Sub Compact (3/1,5mm)**
  - **3 Längen: 45, 60 u. 75 cm**
  - **über Verlängerung oder direkt an Restore anzuschließen**





Verlängerung:

- **Kürzerer Konnektor**
- **Kleinerer Durchmesser**
- **Nur 1 Fixierschraube**
- **3 Längen: 20, 40 und 60cm**

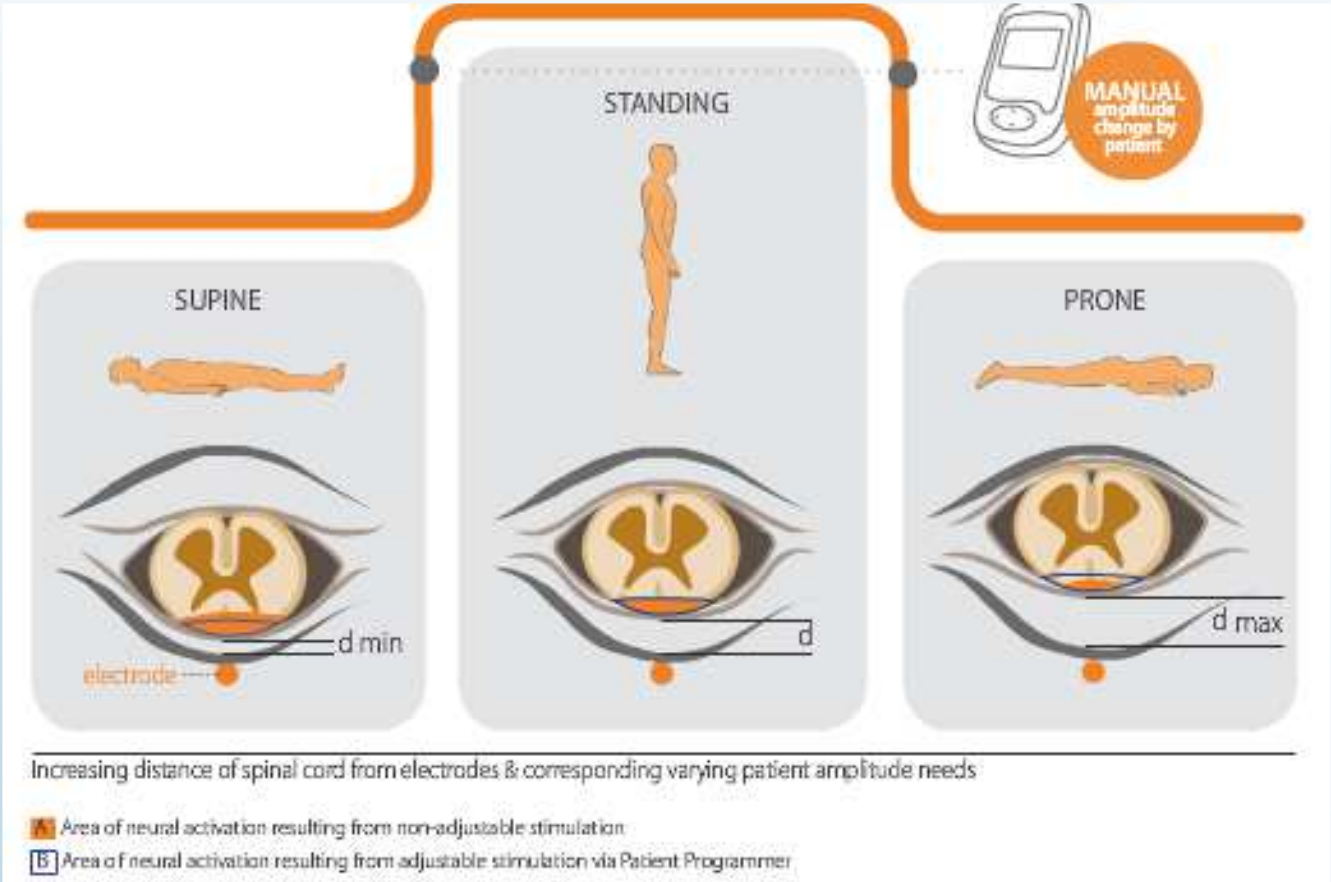


Das Restore ADVANCED™-System

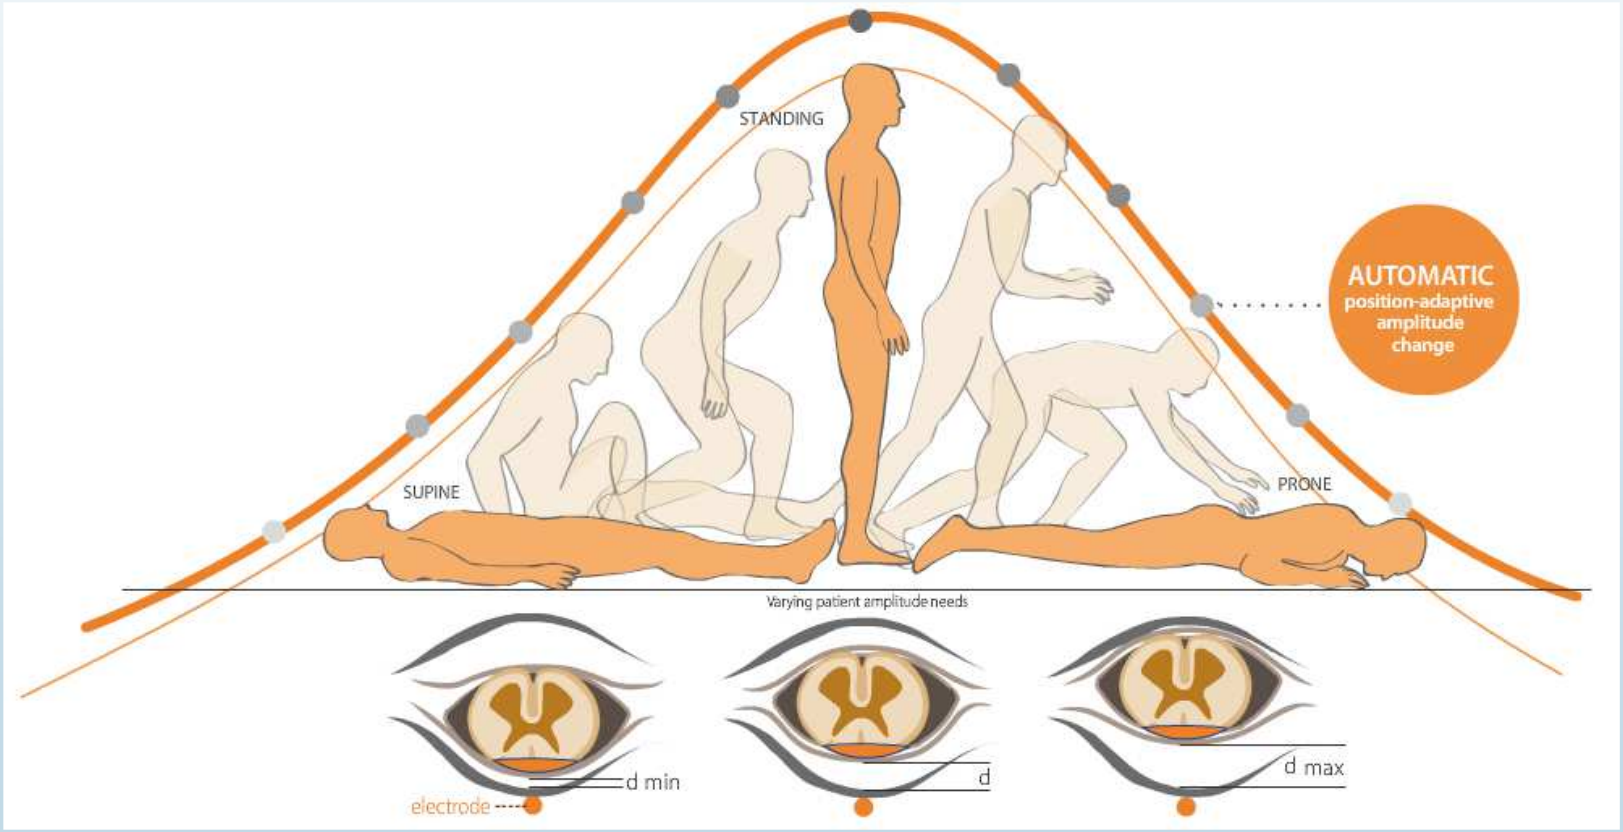
Der Restore ADVANCED™ ist

- **Vollständig kompatibel mit dem Restore™-System**
- **Verbessertes User Interface**
- **Wesentlich eindeutiger in der Bedienung**
  - **Mehr Text, weniger Icons**
  - **Klarer strukturiert**
  - **damit viel einfacher!**
- **Komplett neue Software-Features ... um ein Optimales Ergebnis für den Patienten möglichst rasch zu erreichen**
- **Multiple Delete**
- **Größerer Speicher für bis zu 200 Sitzungen**

Most current neurostimulators require manual adjustment of settings in order to keep stim activation constant



Introducing RestoreSensor™: The Worlds First and Only Neurostimulator to automatically adapt stim settings for position change



The first neurostimulator to offer objective functional data

Table 10. Evidence for DRG in Treating CRPS.

Key statements	Supporting references	Levels of evidence	Recommendation strength	Consensus strength
DRG was effective in treating CRPS type I or type II of the lower extremity.	Deer et al. 2017 (23)	I	A	Strong
DRG stimulation of the upper extremity for CRPS type I or type II requires more study.	Deer et al. 2017 (23)	II-2	A	Strong
DRG achieved improved results for patients with CRPS compared to SCS.	Deer et al. 2017 (23)	I	A	Strong

Deer TR, Pope JE, Lamer TJ et al.The Neuromodulation AppropriatenessConsensus Committee on Best Practices forDorsal Root Ganglion Stimulation. Neuromodulation 2019; 22: 1–35

Table 11. Evidence for DRG in Treating Peripheral Neuropathies.

Key statements	Supporting references	Levels of evidence	Recommendation strength	Consensus strength
DRG stimulation may be effective for the pain of diabetic peripheral neuropathy.	Schu et al. 2015 (86) Eldabe et al. 2017 (87)	III	C	Strong
No recommendations can be made for other forms of peripheral neuropathy, but considering the orientation of the pain, patients should be implanted on a case-by-case basis.	Falowski et al. 2017 (88)	III	B	Moderate

Deer TR, Pope JE, Lamer TJ et al.The Neuromodulation AppropriatenessConsensus Committee on Best Practices forDorsal Root Ganglion Stimulation. Neuromodulation 2019; 22: 1–35

Table 12. Evidence for Chronic Postsurgical Pain.

Key statements	Supporting references	Levels of evidence	Recommendation strength	Consensus strength
In a small prospective, noncontrolled study, DRG stimulation demonstrated relief of CPSP.	Espinet 2015 (91)	III	B	Moderate
Preliminary data from this prospective study suggests that stimulation of the DRG may be an effective intervention for CPSP.	Liem et al. 2014 (92)	III	B	Strong
After six months, VAS and BPI scores decreased significantly. The median satisfaction rating with the overall therapy was 8.0 out of 10.0.	Breel et al. 2016 (93)	III	B	Strong

Deer TR, Pope JE, Lamer TJ et al.The Neuromodulation AppropriatenessConsensus Committee on Best Practices forDorsal Root Ganglion Stimulation. Neuromodulation 2019; 22: 1–35

Table 13. Evidence for Phantom Limb Pain.

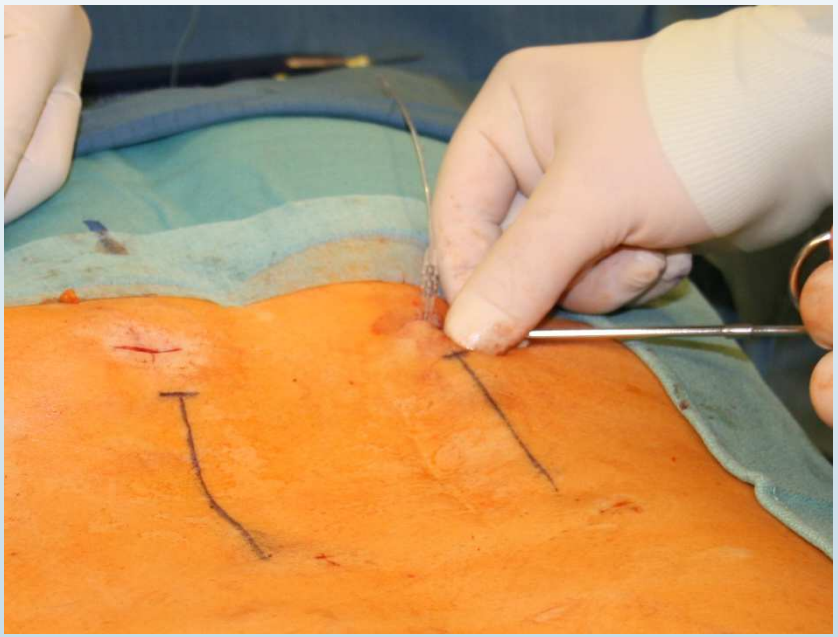
Key statements	Supporting references	Levels of evidence	Recommendation strength	Consensus strength
DRG stimulation may be effective for phantom limb pain.	Eldabe et al. 2015 (22) Hunter et al. 2017 (64)	III	I	Moderate

Deer TR, Pope JE, Lamer TJ et al.The Neuromodulation AppropriatenessConsensus Committee on Best Practices forDorsal Root Ganglion Stimulation. Neuromodulation 2019; 22: 1–35

Table 14. Evidence for Postherpetic Neuralgia.

Key statements	Supporting references	Levels of evidence	Recommendation strength	Consensus strength
DRG is efficacious for postherpetic neuralgia.	Vesper et al. 2016 (104)	II-2	I	Moderate
	Sullivan et al. 2015 (105)	II-2	B	
	Yang et al. 2013 (106)	II-2	C	
	Yanamoto et al. 2012 (107)	III	B	
DRG stimulation is safe for postherpetic neuralgia.	Vesper et al. 2016 (104)	II-2	I	Strong
	Sullivan et al. 2015 (105)	II-2	B	

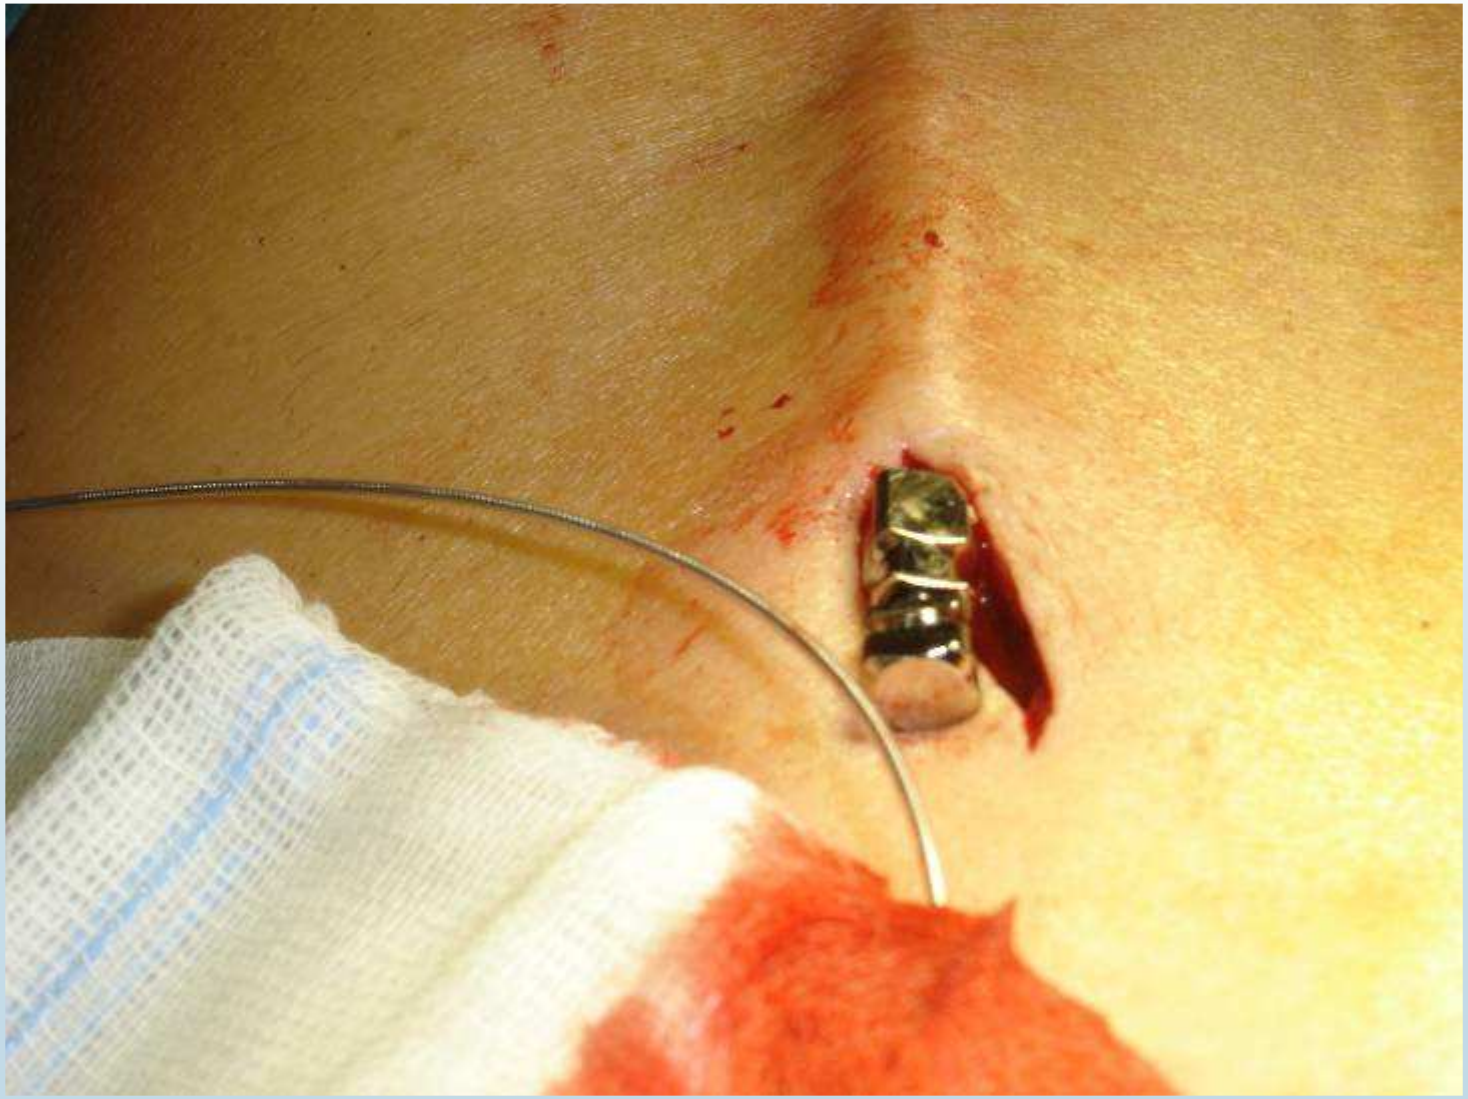
What is Subcutaneous Stimulation?

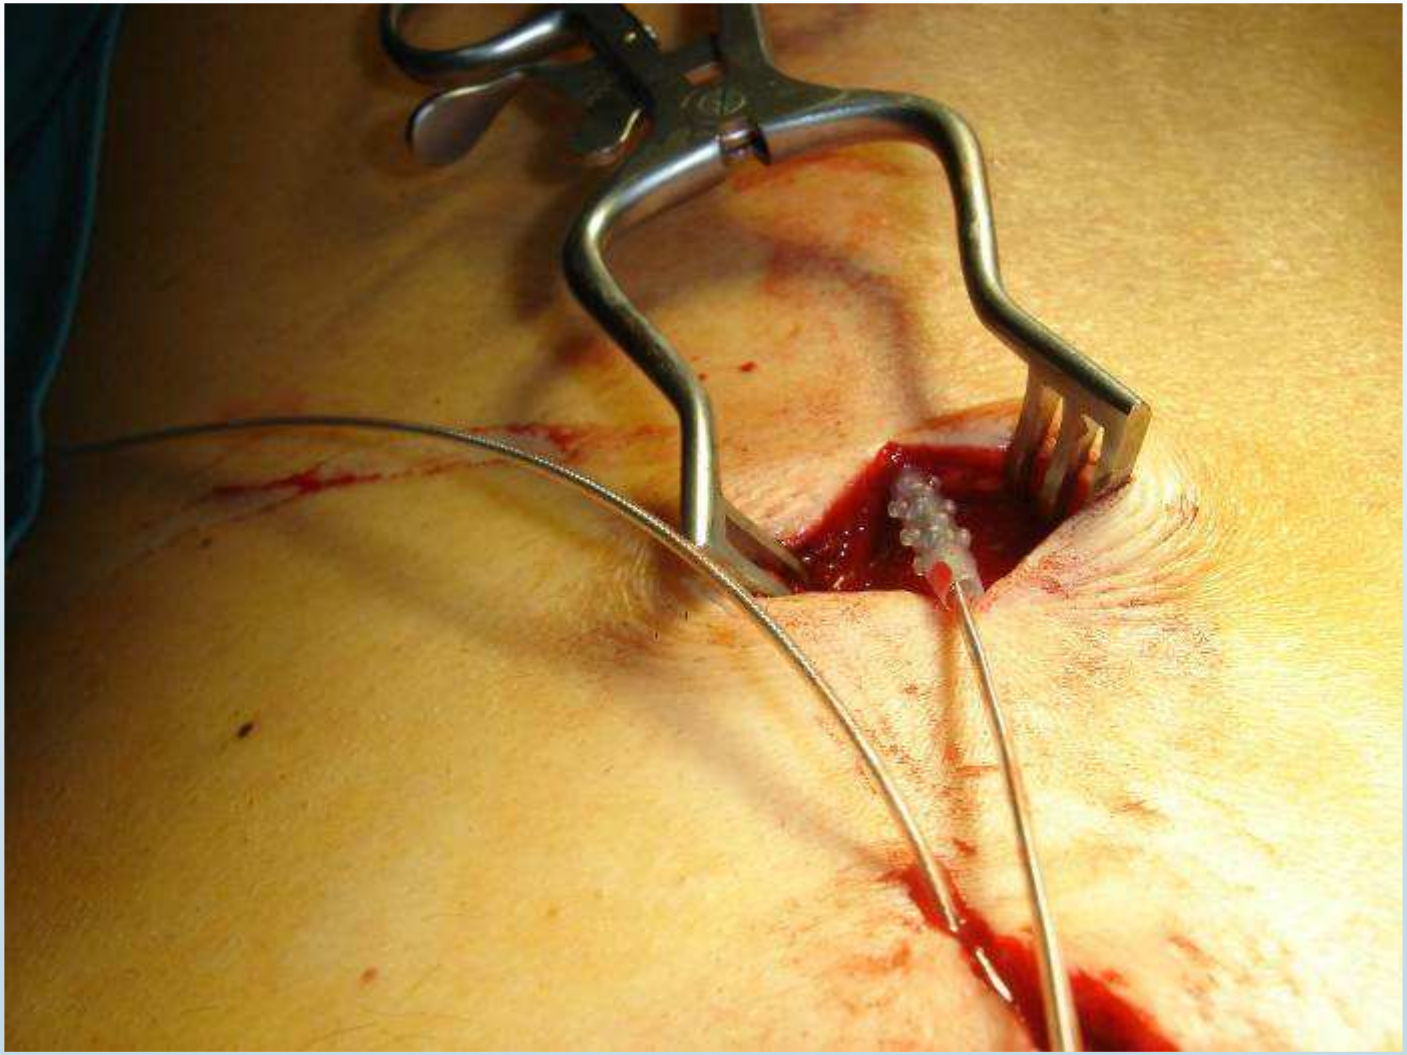


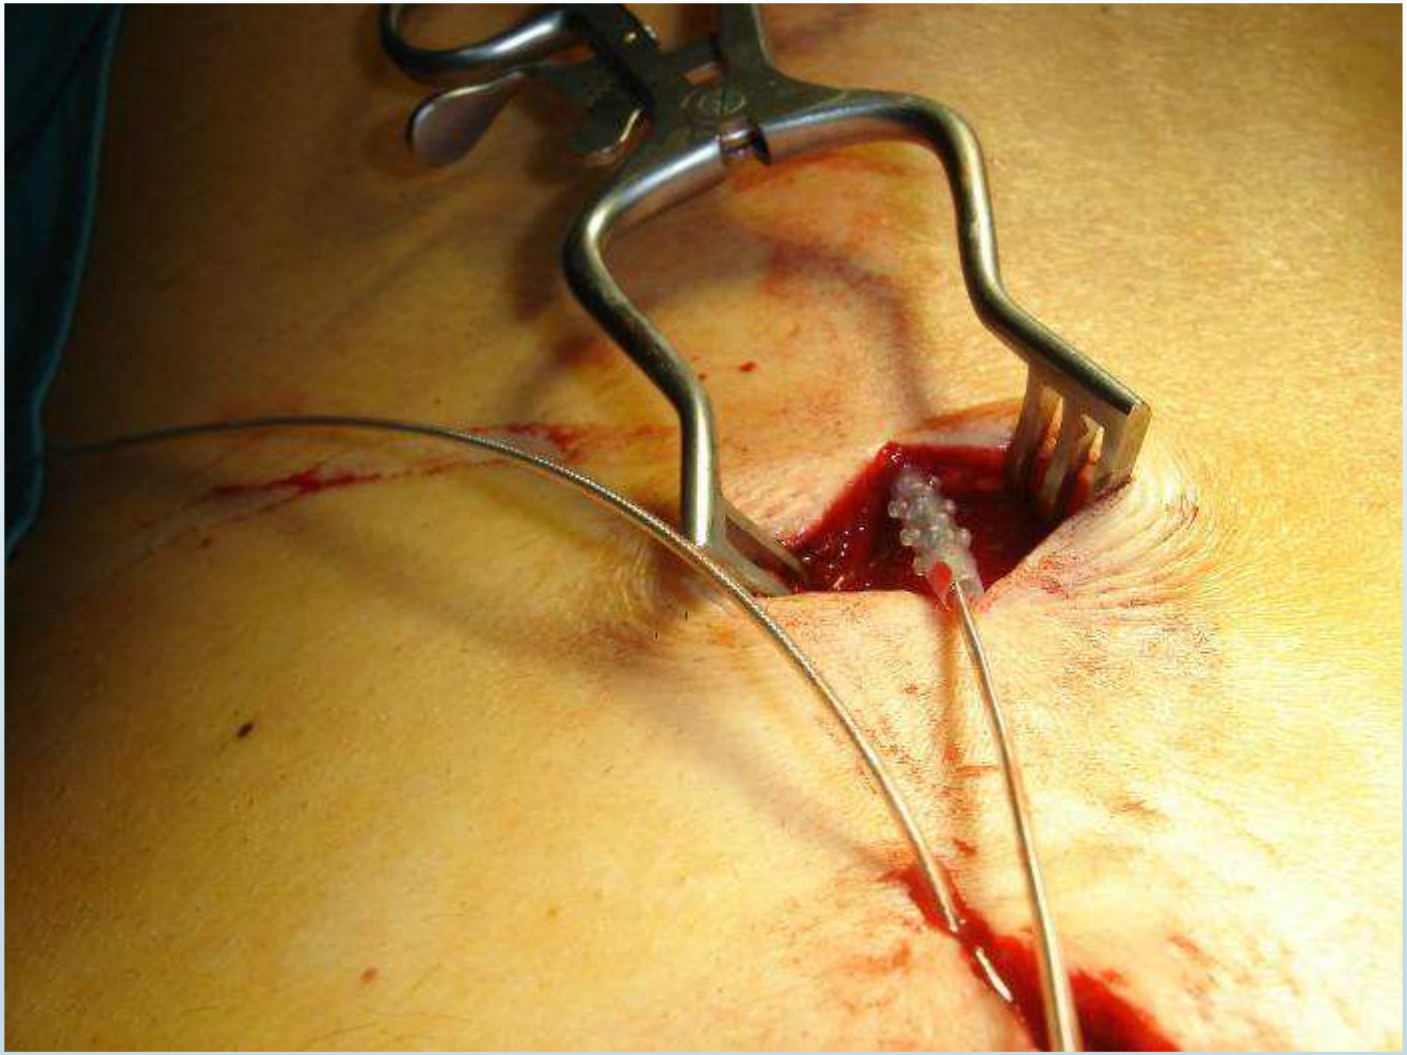
- ⇨ leads placed in the area of pain
- ⇨ right in the subcutaneous tissue
- ⇨ Cave: not too deep!
- ⇨ you should feel the Tuohy needle

Subkutane Stimulation

- **Evaluierung,TENS Therapie?**
- **Welche Elektroden vorzugsweise für welche Indikation?**
- **Wohin und wie tief sollen die Elektroden gelegt werden?**
- **Welche Befestigungstechniken werden empfohlen?**
- **Soll intraoperativ getestet werden? Wenn ja, welche Vorgangsweise wird empfohlen – ohne Lokalanästhetika, mit wenig Lokalanästhetika?**
- **Schmerzlinderung mehr als 50% ?**
- **Paresthesieabdeckung mehr als 80% ?**
- **Verwendung von Antibiotika?**
- **Sollte postoperativ getestet werden? Wenn ja, wie lange – zu Hause?**







111 Patienten mit fokalen chronischen nicht Tumorschmerz wurden in die retrospektive Analyse eingeschlossen.
Indikation für subcutane Feldstimulation war low back pain n = 29, failed back surgery n = 37, Schmerzen in der HWS-Region n = 15, postherpetischen Neuralgie n = 12.
Nach der Implantation war die Schmerzreduktion mehr als 50 %, von 8.2 auf 4.0.
Elektrodendislokation in 14 Patienten (13 %), Infektion in 7 (6 %) und in 6 Fälle (5 %) kam es zum Elektrodenbruch.

"Austrian Subcutaneous Registry"

- **Design:**
  - ⇨ Physician initiated trial
  - ⇨ Prospective Registry
  - ⇨ Multi-center
  - ⇨ Started: 03/2008
  - ⇨ End of patient enrollment: 03/2011
  - ⇨ Follow-Up: 1, 3, 6 and 12 months after lead implant
    - ⇨ extended to 5 years, 6 months interval

- **Inclusion Criteria:**
  - ⇨ Medically refractory patients
  - ⇨ Chronic pain for more than 6 months
  - ⇨ Patients that did not have subcutaneous stimulation yet

"Austrian Subcutaneous Registry"

- **Study objectives:**

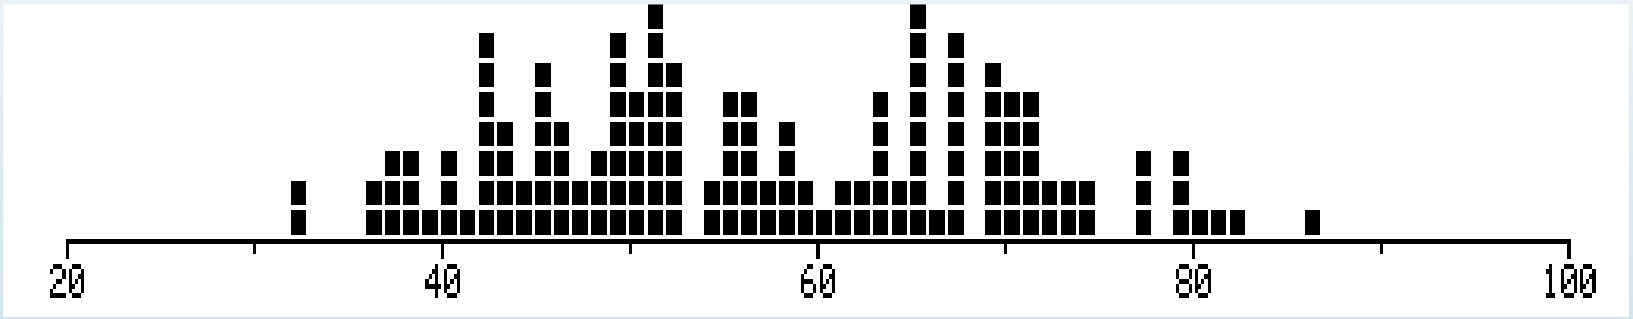
  ⇨ Aim: to assess the efficacy of Subcutaneous Stimulation for chronic pain of different origin, such as

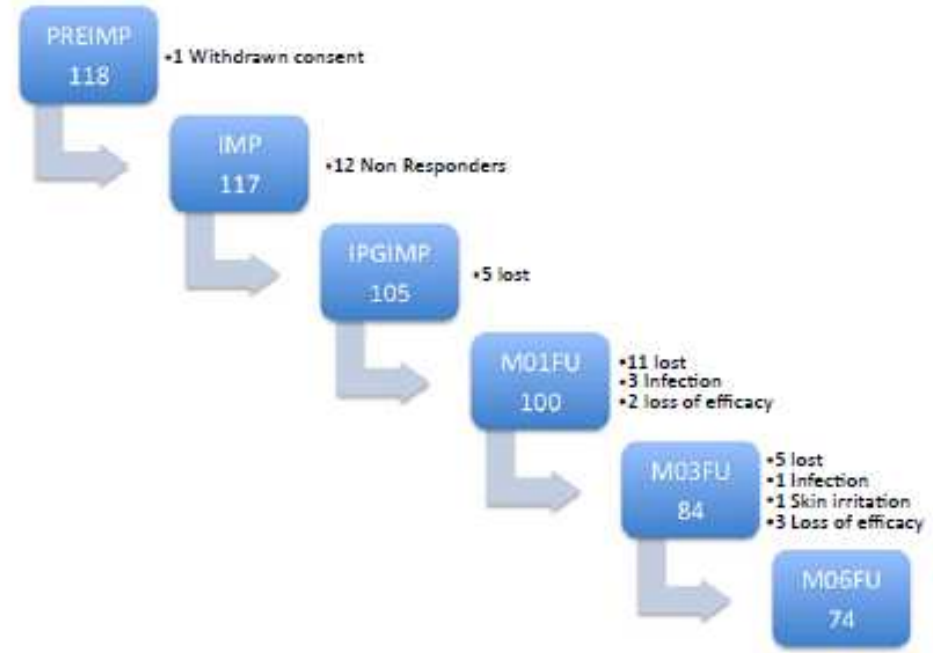
  - Low Back Pain
  - Post Zoster Neuralgia
  - Tension Headache
  - Trigeminal Neuropathy
  - Upper Cervical Syndrome
  - Occipital Neuralgia
  - Cluster Headache
  - Migraine

  ⇨ Endpoints:

  - effect on pain and QoL (VAS, SF12, Oswestry, BDI, …)
  - effect on medication

Age Distribution Patients





Patients' flow chart: PREIMP, screening visit; IMP, test electrodes implanted; IPGIMP, implantation of permanent stimulation device; M01FU, one month follow-up; M03FU, three months follow-up; M06FU, six months follow-up.

Adverse Events & Complications for all 118 LBP patients enrolled

- Explantation of the system

  - 3 x due to infection of the leads (M01FU-M03FU)
  - 1 x due to infection of the leads (M03FU-M06FU)
  - 1 x due to skin irritation at IPG pocket site (M03FU – M06FU)
  - 2 x because of unpleasant stimulation (1 M01FU-M03FU, 1 M03FU-M06FU)
  - 3 x due to loss of efficacy

- AE ratio: 8,5%

In this section the question of whether the type of antibiotics administration („single shot" – SS or continuous" – CS) has an effect on the occurrence of infection is examined.

Breakdown based on number of patients: (p = 0,62)

	Antibiotic-Scheme			
Infection	SS		CS	
yes	2	6%	7	6%
no	29	94%	104	94%
	31	100%	111	100%

Conclusion

- ⇨ 118 Low Back Pain patients included
  - ⇨ considerably long follow-up time: 6 months

Results are promising, as

- ⇨ Mean pain reduction:
  - ⇨ - 45,3% (VAS 8,3 ⇨ 4,6) after 6 months
- ⇨ Quality of Life (Oswestry):
  - all: -11,4% 55,9 ⇨ 48,6 (6M)
- ⇨ Considerable reduction in medication: baseline - 6 months
  - ⇨ Opioid dosage:111 ⇨ 66 mg/day (- 41%)
  - ⇨ Opioid count: reduction 44%
  - ⇨ NSAIDs count: reduction 58%
  - ⇨ Anticonvulsants count: reduction 53%

CONCLUSION

PNFS can be considered as a promising effective therapy option for patients suffering from cLBP.

The technique of PNFS shows much less side effects than common medical therapy and in many cases even more effective.

In our presented data, PNFS seems to be a safe and reversible treatment option of cLBP with no loss of efficacy in the long run.

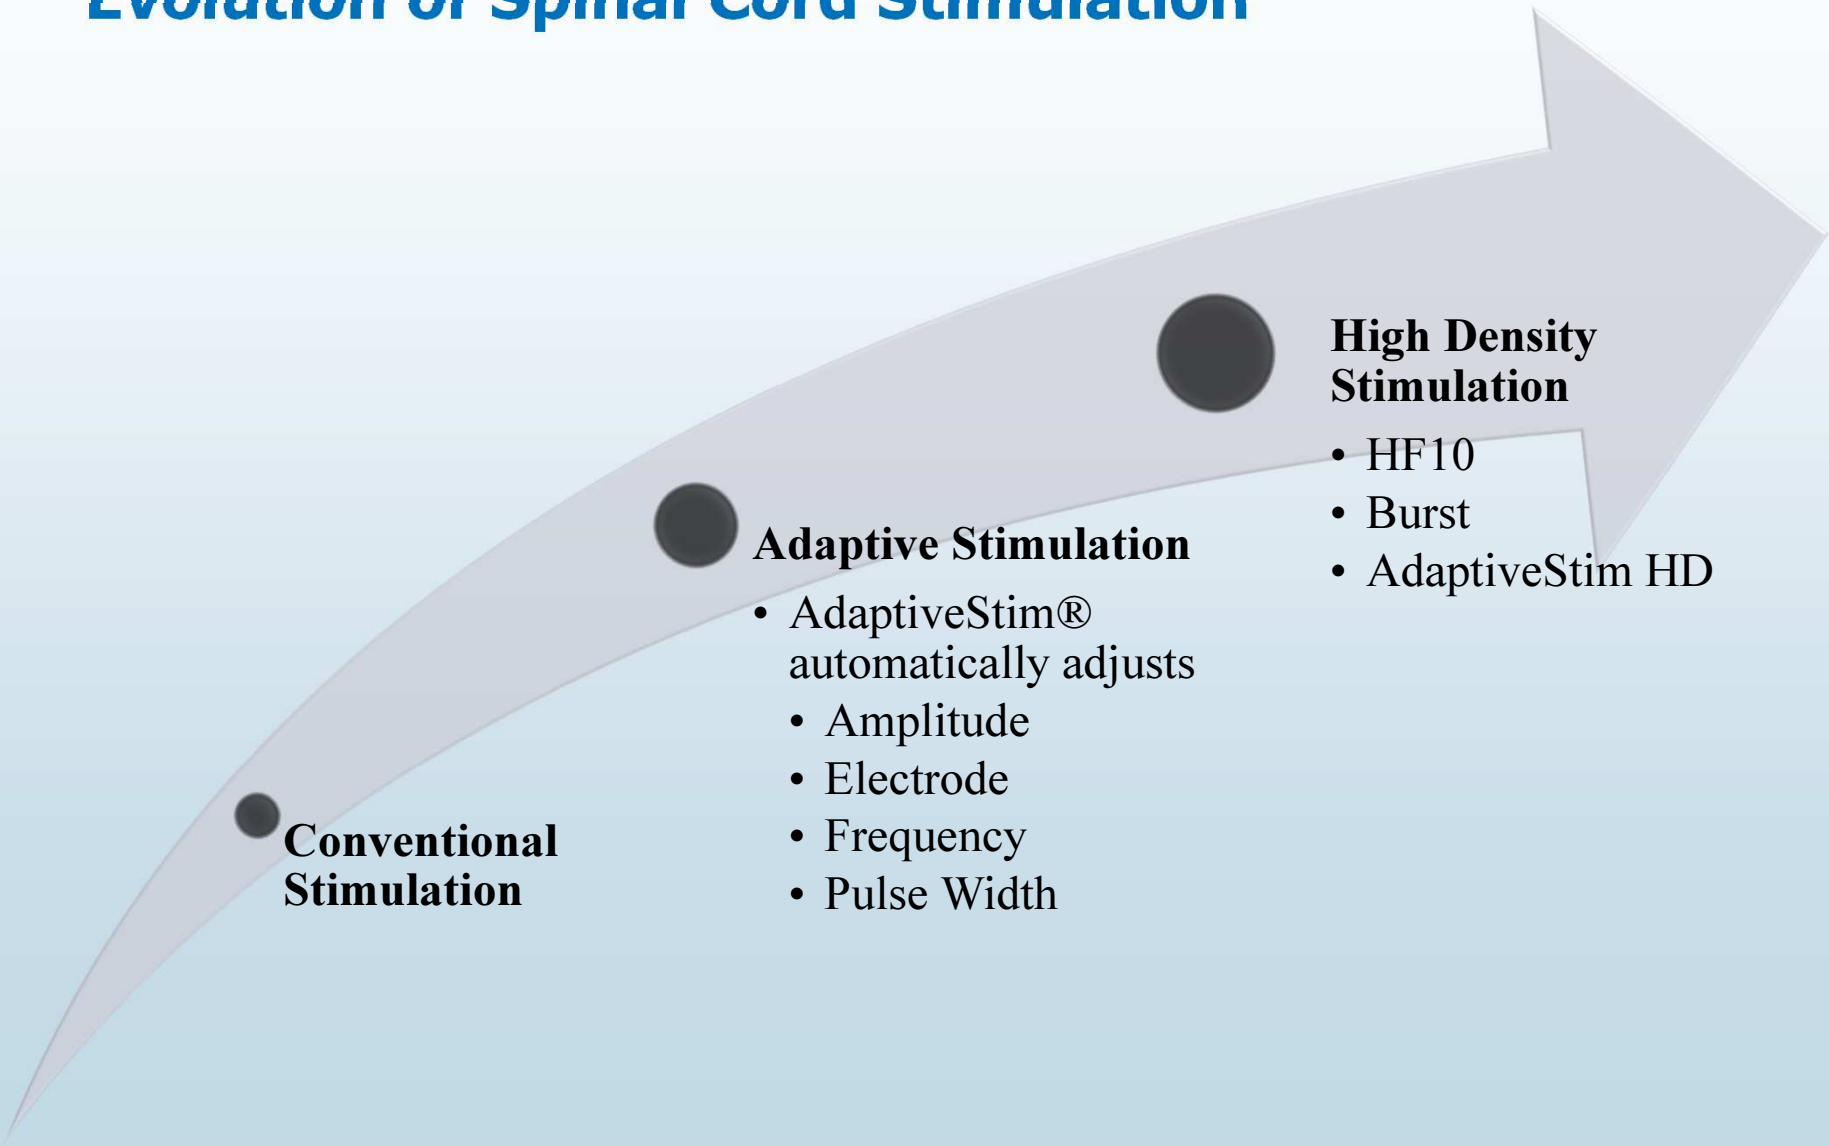
Evolution of Spinal Cord Stimulation



High-Frequency Spinal Cord Stimulation for the Treatment of Chronic Back Pain Patients: Results of a Prospective Multicenter European Clinical Study

Jean-Pierre Van Buyten, MD1*, Adnan Al-Kaisy, MD1†, Iris Smet, MD*, Stefano Palmisani, MD†, Thomas Smith, MD†

Objective: The objective of this prospective, open-label, multicenter European clinical trial was to quantify the efficacy and safety

of a spinal cord stimulation (SCS) system that utilizes high-frequency (up to 10 kHz) waveforms, which do not produce paresthesia,

for the treatment of chronic, intractable pain of the back and/or limbs.

Material and Methods: Eighty-three patients, with significant back pain, were recruited for a trial of high-frequency stimulation

through two percutaneous eight-contact epidural leads. Patients' pain ratings, disability, sleep disturbances, and satisfaction, as

well as complication rates, were assessed for up to six months.

Results: After a trial period, 88% (72 out of 82) of patients reported a significant improvement in visual analog scale (VAS) scores

and underwent permanent implantation of the high-frequency SCS system. Mean back pain VAS of 8.4 was reduced to 2.7 at six

months ($p < 0.001$). Mean leg pain VAS of 5.4 was reduced to 1.4 at six months ($p < 0.001$). Seventy-four percent of patients had

greater than 50% back pain relief at six months. There were significant improvements in Oswestry disability score and sleep, and

reductions in pain medication use. Adverse events observed were those seen with conventional SCS therapy—lead migration,

wound infection, and pain around implant site.

Conclusions: In a cohort of patients with difficult-to-treat chronic back pain, high-frequency SCS provided significant and

sustained low back pain and leg pain relief to more than 70% of treated subjects. Notably, this was achieved without paresthesia.

Patients also experienced significant improvement in disability and sleep. Overall, the results confirm a favorable safety and

efficacy profile of the high-frequency SCS system.

T8
T12

Results. After a trial period, 88% (72 of 82) of patients reported a significant improvement in pain scores and underwent the permanent implantation of the system. Ninety percent (65 of 72) of patients attended a 24-month follow-up visit. Mean back pain was reduced from 8.4 ± 0.1 at baseline to 3.3 ± 0.3 at 24 months ($P < 0.001$), and mean leg pain from 5.4 ± 0.4 to 2.3 ± 0.3 ($P < 0.001$). Concomitantly to the pain relief, there were significant decreases in opioid use, Oswestry Disability Index score, and sleep disturbances. Patients' satisfaction and recommendation ratings were high. Adverse Events were similar in type and frequency to those observed with traditional SCS systems.

Conclusions. In patients with chronic low back pain, HF10 SCS resulted in clinically significant and sustained back and leg pain relief, functional and sleep improvements, opioid use reduction, and high patient satisfaction. These results support the long-term safety and sustained efficacy of HF10 SCS.

Sustained Effectiveness of 10 kHz High-Frequency Spinal Cord Stimulation for Patients with Chronic, Low Back Pain: 24-Month Results of a Prospective Multicenter Study

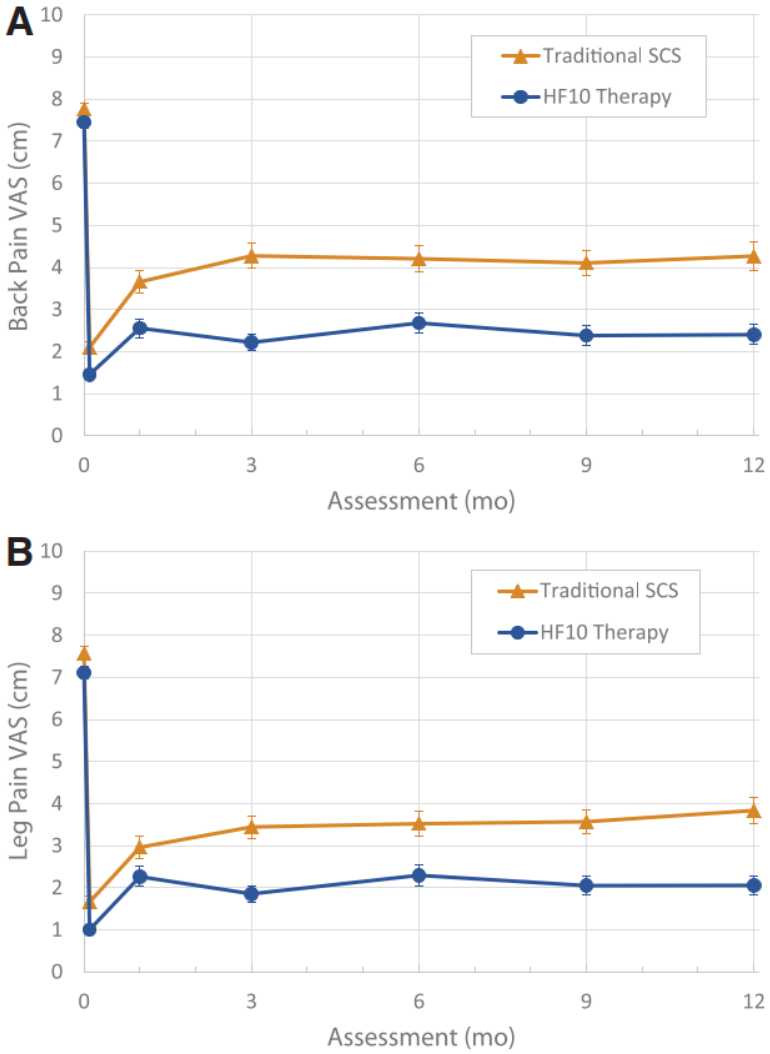
What We Already Know about This Topic

- Spinal cord stimulation (SCS) often relieves radicular pain but is relatively poorly effective for the treatment of back pain
- High-frequency SCS may improve the efficacy of SCS for the treatment of low back pain

What This Article Tells Us That Is New

- This randomized trial involving 198 participants demonstrated that high-frequency spinal cord stimulation (SCS) was superior to conventional SCS for the treatment of back pain and leg pain
- The effects of high-frequency stimulation relative to conventional stimulation persisted for 12 months

Kapural L, Cong Y, Doust MW et al. Novel 10-kHz High-frequency Therapy (HF10 Therapy) Is Superior to Traditional Low-frequency Spinal Cord Stimulation for the Treatment of Chronic Back and Leg PainThe SENZA-RCT Randomized Controlled TrialAnesthesiology 2015; 123:851-60



Longitudinal back and leg pain visual analog scale (VAS) scores. Values at time 0 represent baselines scores, whereas values at time 0.1 represent results at the end of trial phase. Chronic pain is a common condition that affects the physical, emotional, and mental well-being of patients and can significantly diminish their quality of life.

Due to growing concerns about the substantial risks of long-term opioid use, both governmental agencies and professional societies have recommended prioritizing the use of nonpharmacologic treatments, when suitable, in order to reduce or eliminate the need for opioid use.

The use of 10 kHz spinal cord stimulation (10 kHz SCS) is one such nonpharmacologic alternative for the treatment of chronic, intractable pain of the trunk and limbs.

This review examines published clinical data regarding the efficacy of 10 kHz SCS for decreasing chronic pain in patients and its potential to reduce or eliminate opioid usage.

Multiple prospective and retrospective studies in patients with intractable pain demonstrated that 10 kHz SCS treatment provided ≥50% pain relief in >70% patients after at least 1 year of treatment. Pain relief with 10 kHz SCS therapy ranged from 54% to 87% in the studies.

More importantly, the mean daily dose of opioids required by patients in these studies was reduced after 10 kHz SCS treatment, and on average over 60% patients in studies either reduced or eliminated opioids at the last follow-up.

EVOLVE^{SM} WORKFLOW
WHY 1000 Hz & 90 µSEC

PREDEFINED HD PARAMETERS

WHY FOCUS ON 1000 HZ & 90µs?

- The Options Study suggests that patients respond to the HD setting of 1000 Hz, 90 µsec.
- Additionally, published literature shows improved NPRS pain scores utilizing 1000 Hz stimulation when compared to baseline.[2]

SCS TRIALING[1]

- 84% (37/44) reported ≥50% improvement in overall pain during the screening trial while programmed to HD.
- 70% of subjects had a successful trial when programmed to 1000 Hz and 90 µsec.

3 Month outcomes (N=32)[1]

- Overall pain change from: baseline -3.7 ($p<0.01$)
- Back pain change from baseline: -3.8 ($p<0.01$)
- Leg pain change from baseline: -4.1 ($p<0.01$)

KEY HIGHLIGHTS FROM VECTORS 6 MONTH RESULTS:

- Pain relief was statistically significant at 3-Months (primary outcome) and was sustained through 6-Month follow up.
- Responder rates (≥50% reduction in pain) at 6 months were; **67.7%** for Overall Pain, **59.4%** for Low-back pain and **74.0%** for Leg Pain
- Improvements in Quality of Life (EQ-5D) and reduced disability (ODI) remained significant and were sustained between 3-Months and 6-Months follow up.
- Therapy Satisfaction increased from 81% at 3 Months to **90%** at 6 Months.

Conclusions

Results suggest that a positive trial within 3 days is indicative of longer-term pain relief. There is still a potential benefit for a group of patients to have a longer trial experience. Longer-term follow-up data will be useful to better understand the predictive role of trials and the sustained effectiveness of pain relief

- 71% of subjects with a positive trial at Day 3 were overall responders at 3 months
- 70% of subjects with a positive trial at Day 3 were overall responders at 6 months

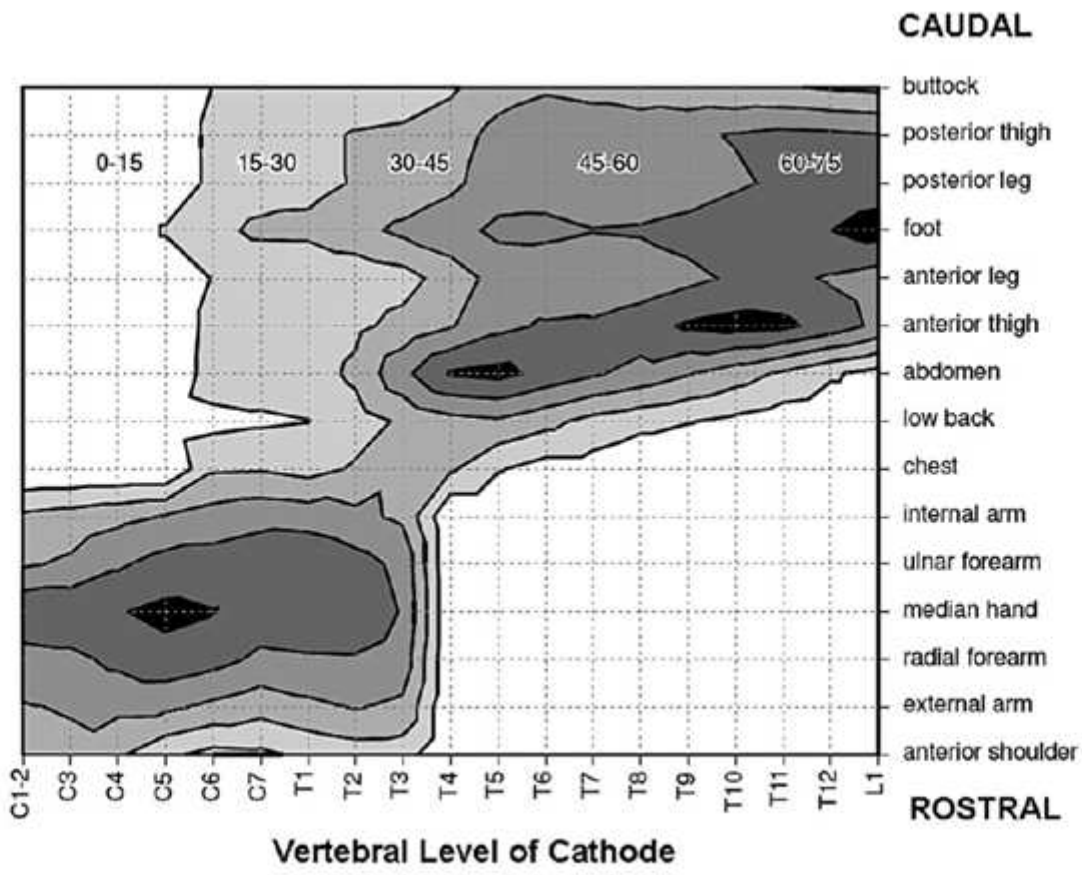
Table 1. Clinical Correlates of Electrical Stimulation of Intraspinal Structures.

Anatomical structure(s)	Clinical correlates	Location in relation to the cathode
Dorsal root/dorsal root entry zone/dorsal horn	Paresthesia	Ipsilateral and at the same spine segment
Dorsal columns	Paresthesia	Ipsilateral and caudal
Ventral (anterior) roots/ventral motor neurons	Motor contractions	Ipsilateral and at the same spine segment
Corticospinal tract	Motor contractions	Ipsilateral and caudal
Spinothalamic tract*	Sensation of warmth	Contralateral and caudal
Autonomic fibers (inhibition of sympathetic fibers)	Sensation of warmth and vasodilation	Ipsilateral and caudal

*Cannot be obtained with dorsal epidural stimulation; has only been observed during the stimulation phase of percutaneous cordotomies.

Molnar G, Barolat G. Principles of Cord Activation During Spinal Cord Stimulation. Neuromodulation 2014; 17: 12–21



Probability of generating paresthesia in a particular body area as a function of vertebral level of the stimulating cathode. Figure modified from Holsheimer J, Barolat G. Neuromodulation. 1998;1 (3):129–136 (28).

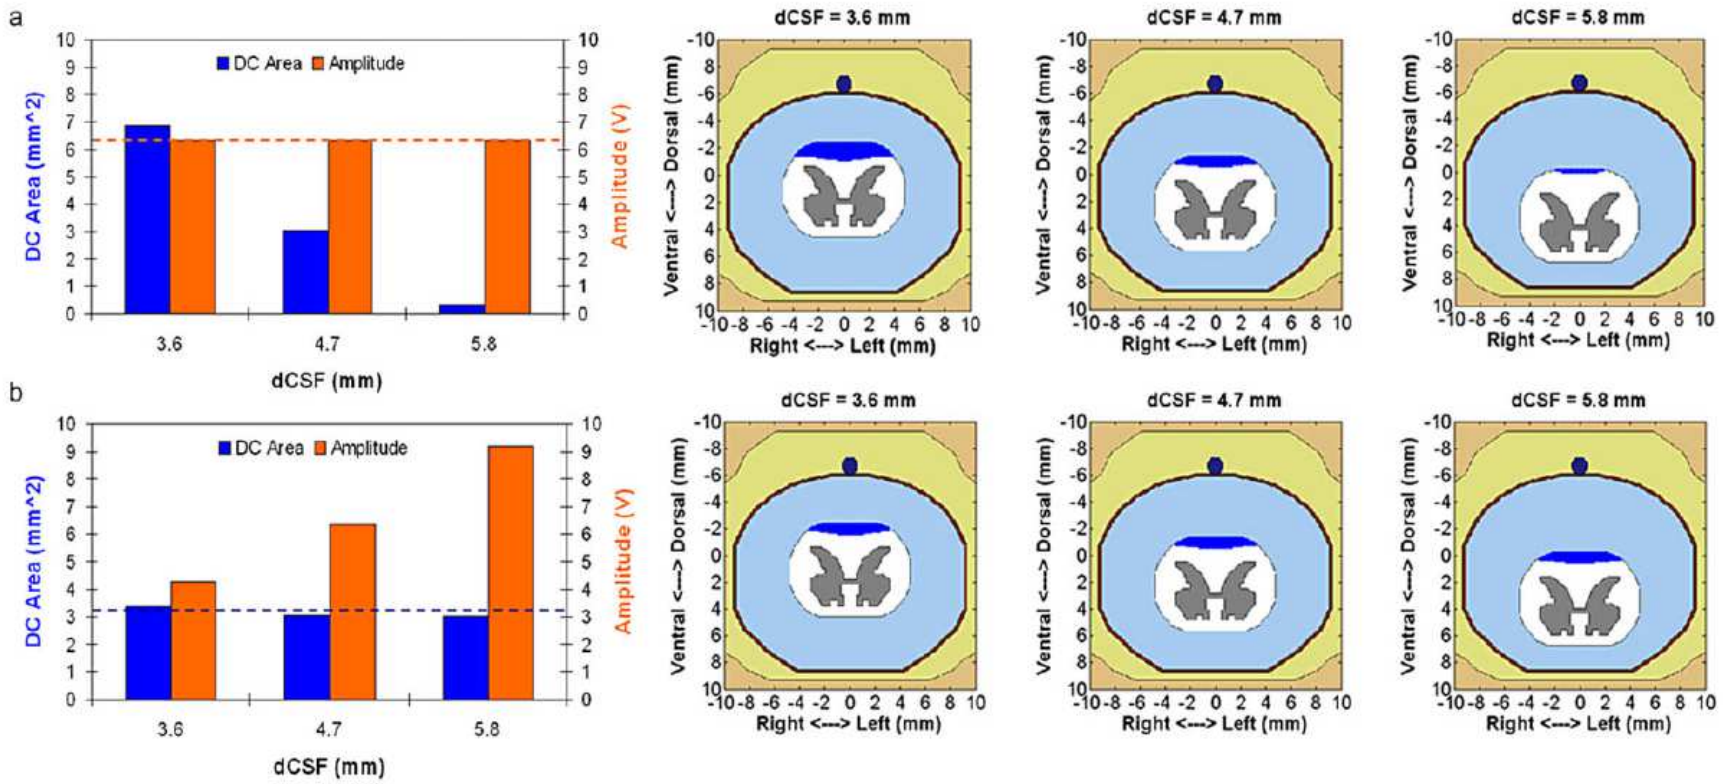
Table 2. Electrical Conductivity of Tissues Used in a Spinal Cord Stimulation Computer Model.

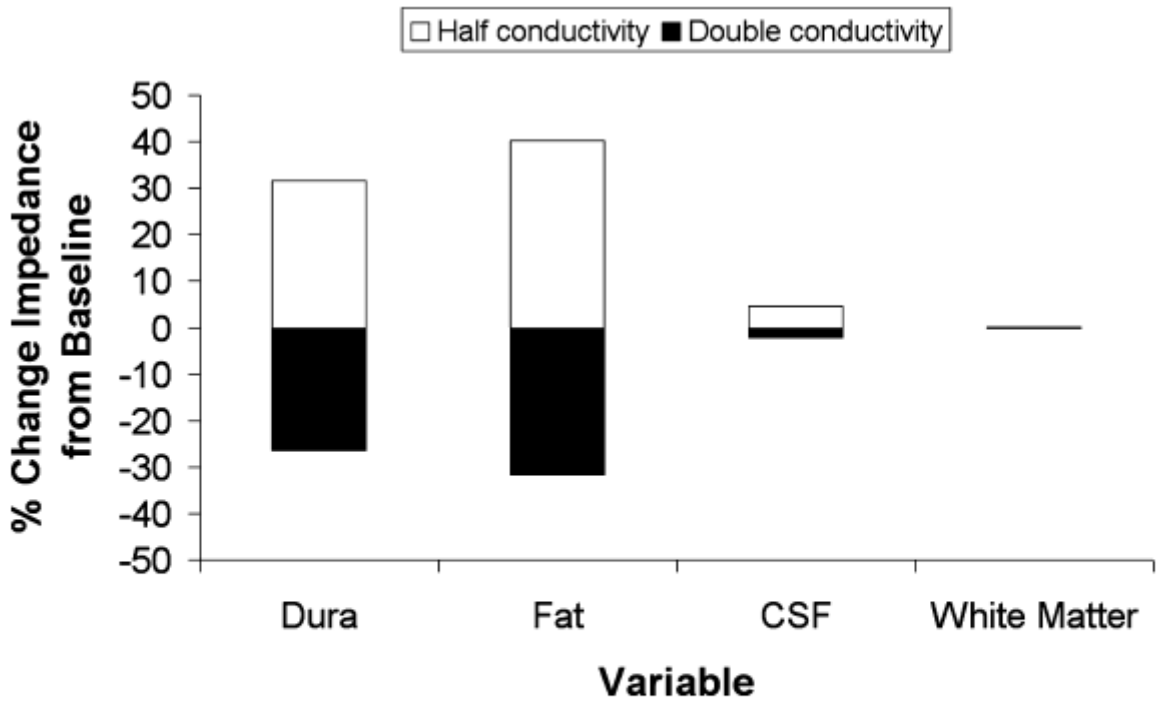
Structure	Conductivity (S/m)
Vertebral bone	0.02
Epidural fat	0.04
Dura mater	0.03
Cerebrospinal fluid (CSF)	1.7
White matter	0.6 longitudinal 0.083 transverse
Gray matter	0.23

Molnar G, Barolat G. Principles of Cord Activation During Spinal Cord Stimulation. Neuromodulation 2014; 17: 12–21



Neural activation patterns generated by varying dCSF (3.6, 4.7, and 5.8 mm) with a guarded cathode configuration and an amplitude at 60% of the usage range using (a) constant amplitude stimulation and (b) varying amplitude stimulation. The figures to the left of the neural activation patterns quantify the dorsal column recruitment area (DC area in mm^2) and stimulus amplitude as a function of dCSF.

Molnar G, Barolat G. Principles of Cord Activation During Spinal Cord Stimulation. Neuromodulation 2014; 17: 12–21



Doubling or halving the electrical conductivity of the tissues near the electrodes (fat, dura) in the spinal cord stimulation model results in larger changes in impedance compared with varying the electrical conductivity of tissues far away from the electrode (CSF or white matter).

Molnar G, Barolat G. Principles of Cord Activation During Spinal Cord Stimulation. Neuromodulation 2014; 17: 12–21

CONCLUSION

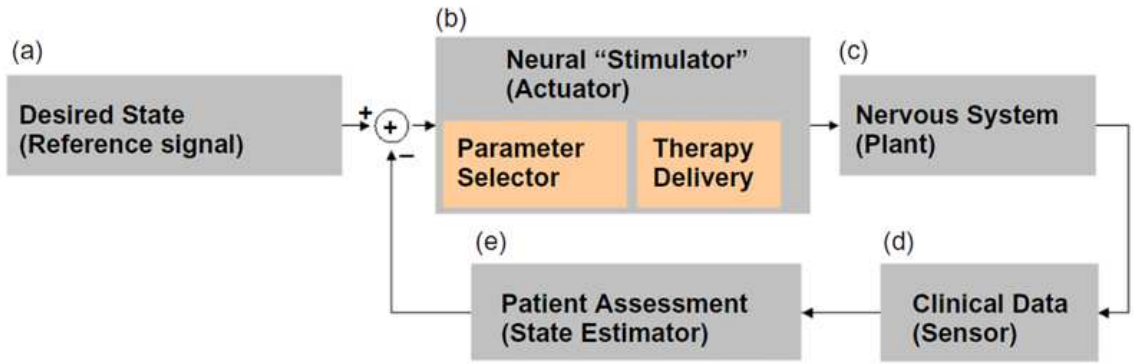
We have reviewed the basic principles of extracellular stimulation and their importance in understanding of the effects during SCS.

The electric field is influenced by the electrical properties of the tissue, the electrode placement and polarity, and the stimulation parameters.

The spatial extent of activation and the types of activated neural elements can be controlled by careful selection of stimulation parameters.

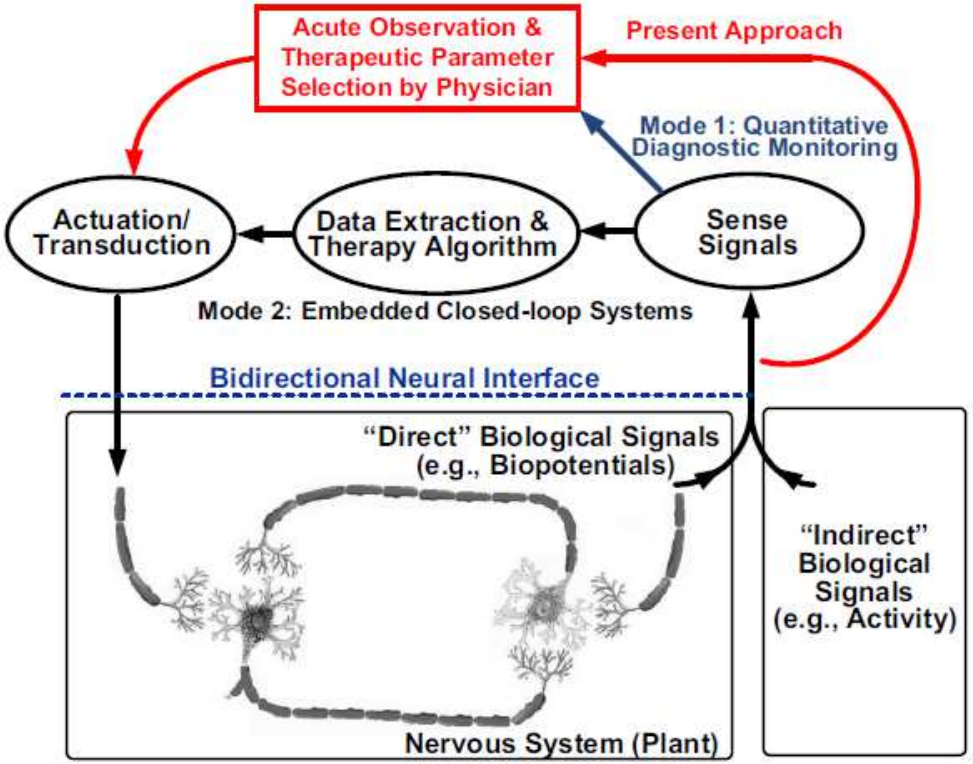
Better understanding of the interaction between the electric fields and the targeted neural elements may guide the selection of stimulation parameters and may lead to advances in engineering solutions for SCS.

Molnar G, Barolat G. Principles of Cord Activation During Spinal Cord Stimulation. Neuromodulation 2014; 17: 12–21



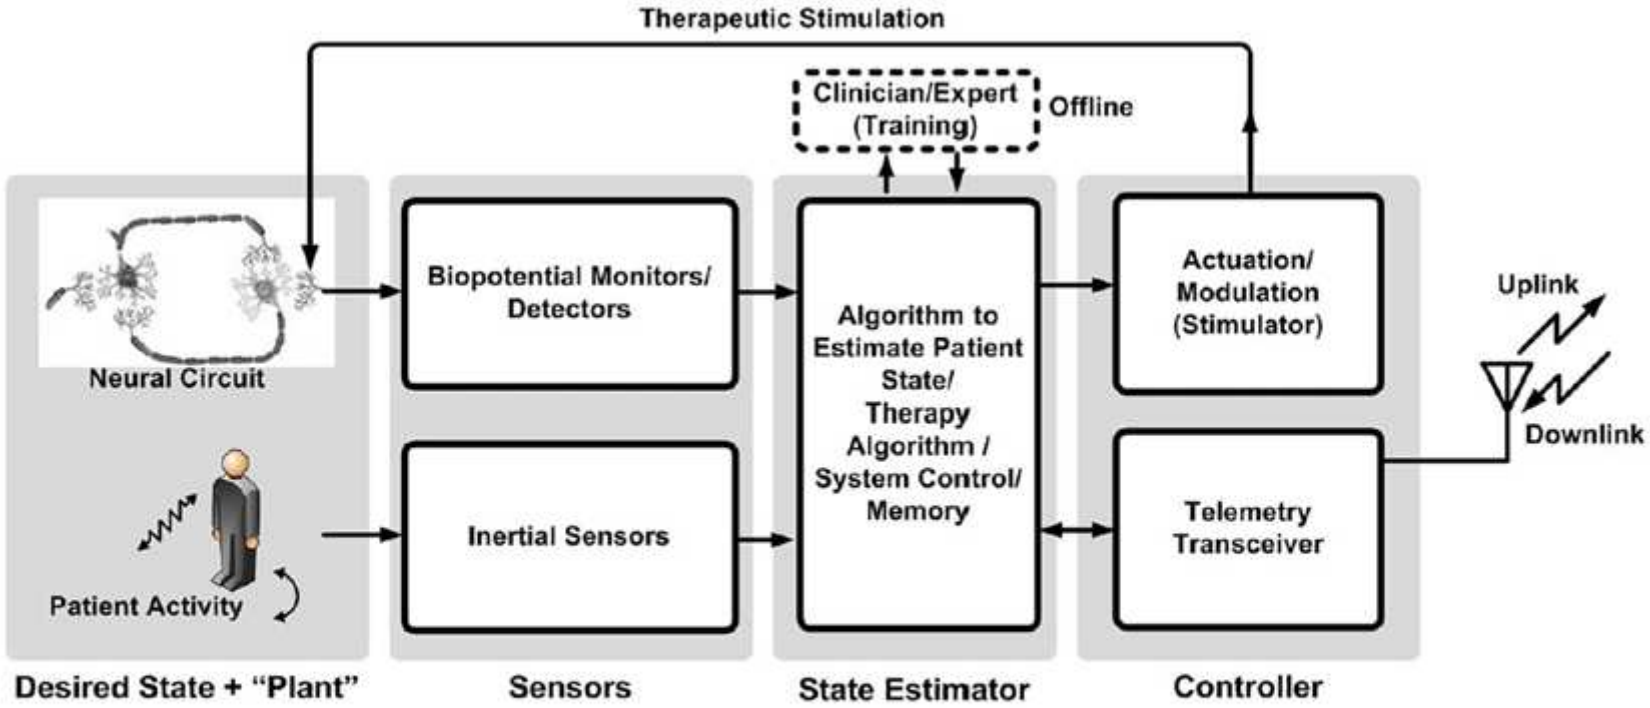
A dynamic control framework for analyzing neuromodulation systems. (a) Desired neurological state is the input reference signal; (b) the neural stimulator is the actuator; (c) the nervous system is the plant; (d) transducers and observations to collect clinical data are the sensors; and (e) patient assessment is the state estimator. In current clinical practice, the difference between a physician's observed estimate of the patient state and the desired clinical state drives parameter changes in the device, with adjustments often limited to sparsely sampled measurements. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



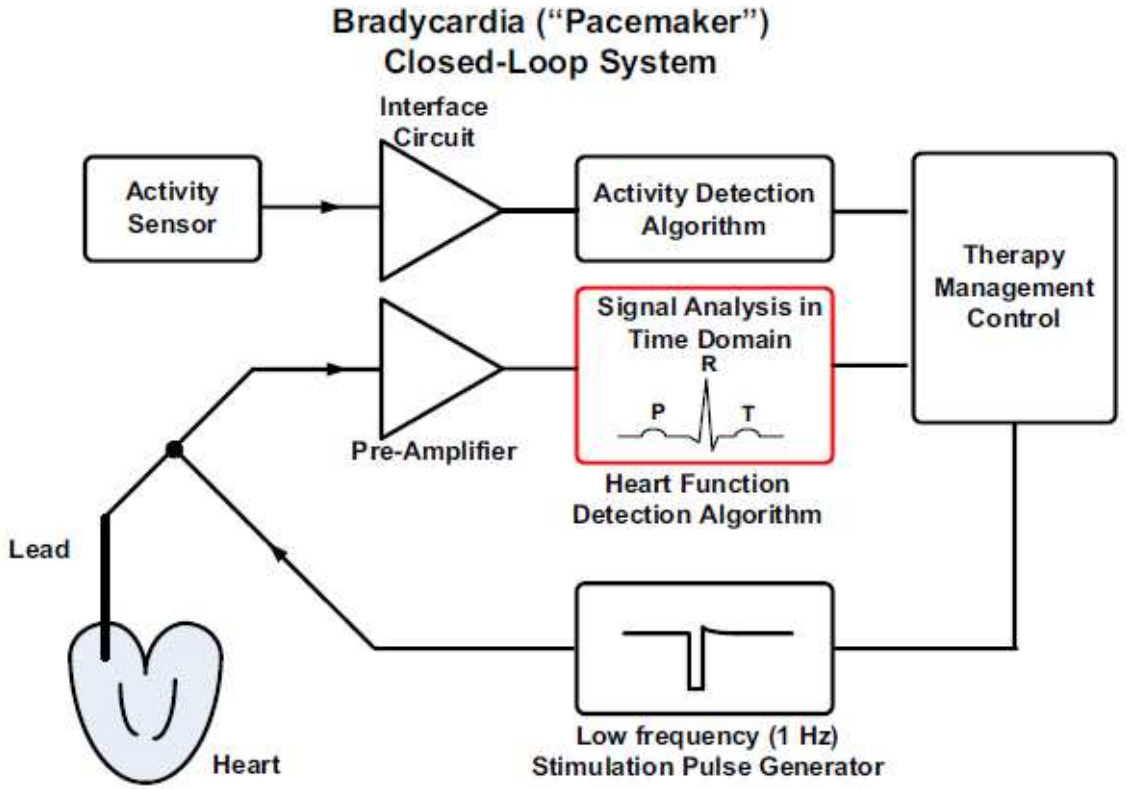
Modeling clinical flow of a patient from a feedback perspective. The pathways can include clinician and/or patient feedback-based symptoms and observations, or be automated with embedded sensors and algorithms. In practice, most neuromodulation devices today are closed loop, but the clinician and patient form the feedback mechanism. Technology can improve these systems through two modes: (1) improving existing feedback paths with enhanced sensing of biomarkers or (2) closing the loop completely within the device. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



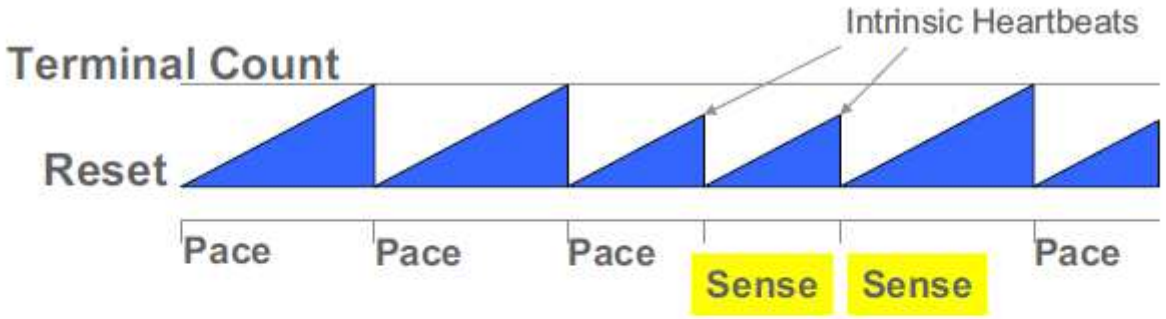
Mapping the abstracted feedback loops to a prototypical stimulator system. The key blocks in the diagram illustrate the technology required for the sensors, state estimator, and controller in a functional stimulator. Note that this is not an exhaustive list of components; for example, other sensors might include biochemical assays, impedance, and so on. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



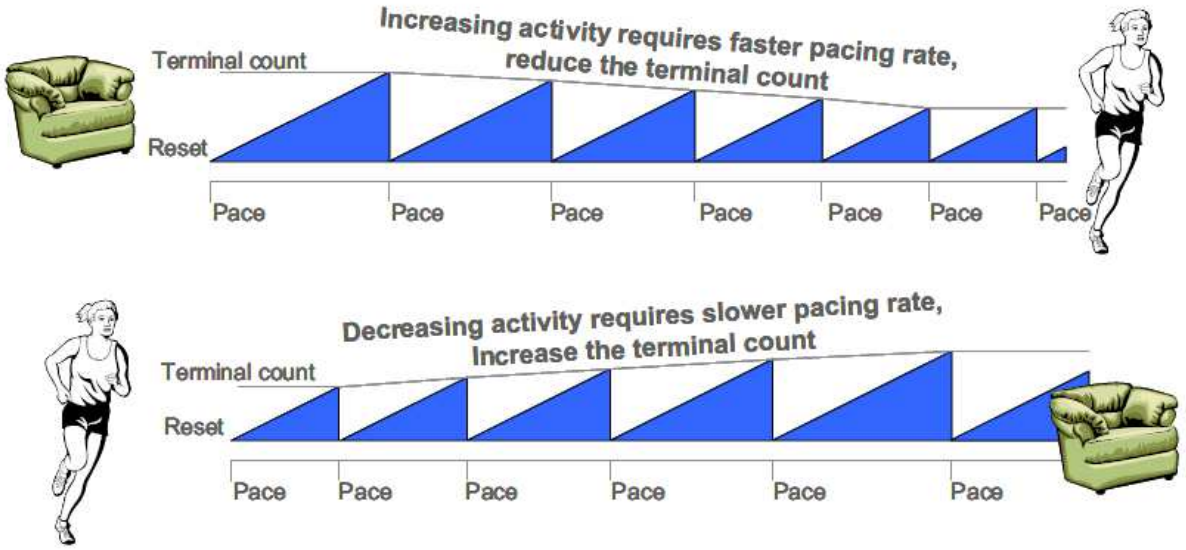
Model for bradycardia pacemaker closed-loop system. Note that there is a direct pathway of sensing physiology through an amplifier and an indirect pathway through an accelerometer. Other sensor inputs such as impedance, pressure, and chemical assays might show promise in the future. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



Inhibitory responsive pacing. A counter increases until hitting a terminal count which, once hit, triggers a heart pace and resets the counter. The terminal count setting determines the minimum pacing rate. Any detected intrinsic heartbeat, measured as an electrocardiogram with a biopotential amplifier attached to the pacing lead, resets the counter without a pacing event. This allows the heart to regulate itself whenever possible and extends battery life. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



Rate-responsive pacing. The terminal count setting still determines the minimum pacing rate, but is set dynamically by monitoring the activity of the patient. The dynamic variation is set by extending the terminal count in proportion to the activity rate (higher activity lowers the terminal variable, leading to a faster required rate). Dynamic thresholds allow for the pacing system to provide more variable hemodynamic settings, which are appropriate to the immediate needs of the patient. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57

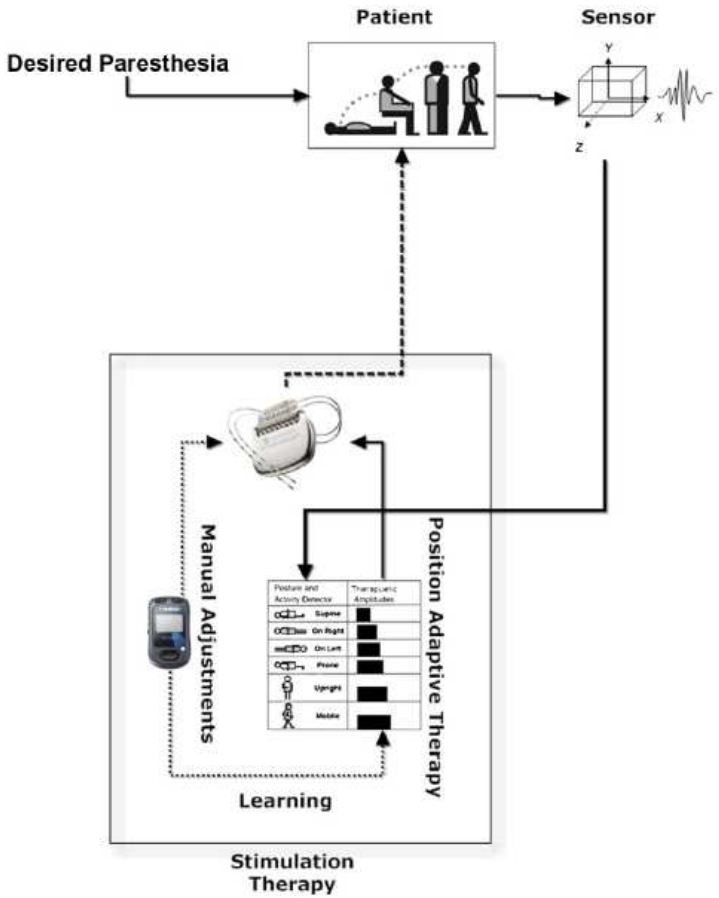
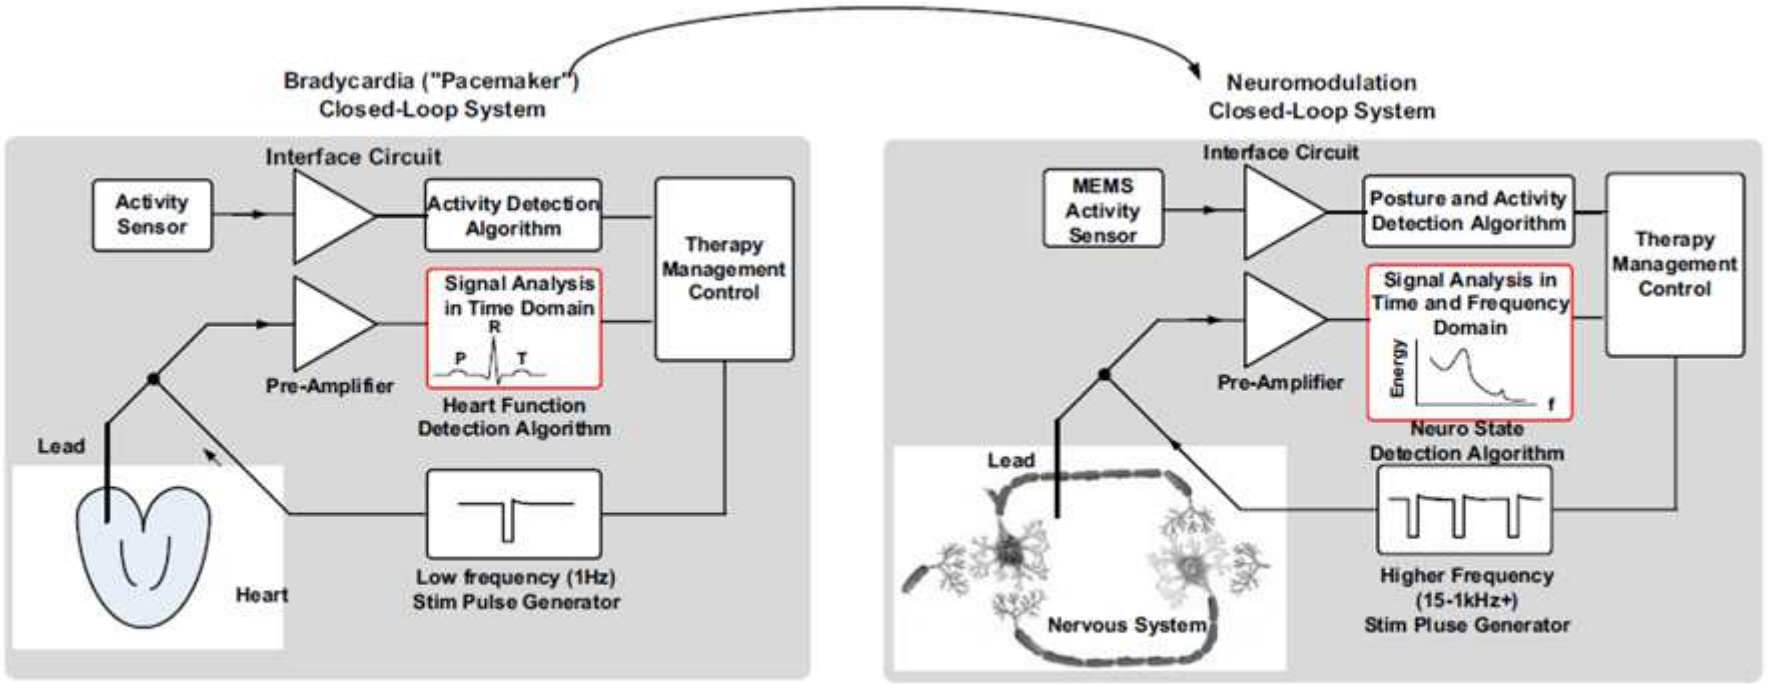
Adding hysteresis for transitions; the concern is that if the patient's posture puts them close to a transition vector, residual noise in the sensor might lead to rapid "chatter" in the actuator settings which might cause discomfort. To prevent this state, hysteresis can be added so that once a transition has been noted in the algorithm, the actuator will not go back to the prior state until a greater rotation occurs. If the hysteresis is designed to be greater than the noise, minimal chatter results. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



A posture-responsive SCS control loop: from the top left, a clinician interactively works with the patient to set desired parameter settings for different posture states. This mapping is then stored within the implantable device. Once the control loop is engaged, the position and activity sensor detects the patient's state and continuously updates the appropriate stimulation parameters based on the mapping. If the optimal settings vary over time, the patient's programmer allows for manual adjustments to compensate, and these settings are passed to the embedded mapping table as the new optimal settings. The patient programmer allows for the system to continue "learning" chronically. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Denison T, Litt B. Advancing Neuromodulation Through Control Systems: A General Framework and Case Study in Posture-Responsive Stimulation. Neuromodulation 2014; 17: 48–57



Mapping pacemaker architectures to neuromodulation systems. Designers must be mindful of the similarities and differences between the cardiac and nervous system to avoid oversimplifying the mapping of existing architectures to future therapies. Note that this representation shows just a handful of the potential sensors and algorithms that might be used in the future. Figure reprinted with permission from Medtronic. © Medtronic, 2014

Preoperative Checklist

KABEG
KLINIKUM KLAGENFURT
AM WÖRTHERSEE

Procedure checklist

Preoperative medical issues

- __Check for evidence of active or potential dermal, dental, urologic, or other infections and treat as necessary.
- __Order urinalysis before procedure. Coordinate with clinical signs and symptoms.
- __Address previous history of infection and make a plan for prophylaxis adjustment.
- __Review MRI of the spine in the past 12 mo depending on diagnosis and planned placement of stimulator tip.
- __Discontinue anticoagulation with approval of treating physician for a length of time before procedure that is appropriate for the specific anticoagulant and surgical bleeding risk. The appropriate timing for discontinuation should be based on the medication half-life and whether the patient is taking the medication for primary or secondary prevention. Consider ASRA guidelines for medication management.[4]
  - Off nonsteroidal anti-inflammatory drugs for one week if desired
  - Off acetylsalicylic acid for seven d
  - Off warfarin or fondaparinux for five d, clopidogrel for seven to ten d, and ticlopidine for 10 to 14 d
- __If patient was on warfarin, order prothrombin time testing on or before the morning of the procedure.
- __Review psychological evaluation and address any recommendations.
- __Examine the potential sites of implantation and battery pocket for infection or inflammatory process.
- __If there are any potential technical or patient-specific concerns, communicate with the treating physician and/or the anesthesiologist before implant.
- __Educate the patient/caregiver(s).
- __Obtain insurance coverage and document medical necessity.

Surgical considerations

- __Assess health status the day of surgery.
- __Have patient empty bladder preoperatively.
- __Consider COVID-19 testing based on local health care policy recommendations.
- __Obtain baseline pain score and review overall goals of the implant.
- __Review postoperative instruction sheet with patient/caregiver preoperatively.
- __Check that adult driver has been arranged to take patient home.
- __Order preoperative antibiotics and administer 30 to 60 min before incision or within two hours for vancomycin. Antibiotic doses should be based on the patient's weight.
- __Arrange for family to observe programming and learn about recharging.
- __Confirm follow-up appointment before discharge.
- __Answer any questions from the patient or caregivers regarding postoperative wound management.

Tissue dissection II. Conventional surgical approach (at the left). Surgical approach consists in separating paraspinal fascia and muscles from the spinous process and ligaments. Once the spinous process and laminae have been exposed, removal of the supraspinous, the interspinous ligament, and the ligamentum flavum is possible thanks to a small gouge or an arthrectomy pinch. Kerrison rongeurs can be used to remove a small portion of the inferior lamina of the upper vertebra to place the lead phantom and then the paddle lead in the epidural space. Aspects of the minimally invasive (MAST) procedure (at the right). Surgical approach on one or both sides of the supraspinous process, with careful dissection of the paravertebral musculature. Full system set. Insertion of the phantom lead and implantation of the lead in the median position, verified by intraoperative x-ray. The aspects of lead implantation angle: a high approach at the thoracic spine level is possible by using the minimally invasive technique. The bony removal can be minimized, and a shallow, safe angle of insertion achieved with a good retractor system and illumination. Photos courtesy of Philippe Rigoard and used with permission.

Absolute criteria for the consideration of SCS, selected by the expert panel

KABEG
KLINIKUM KLAGENFURT
AM WÖRTHERSEE

Inclusion criteria	Exclusion criteria

• Age ≥ 18 years
• Chronic pain with a duration of least 6 months
• One of the following primary indications:
  • Chronic low back/leg pain
  • Complex regional pain syndrome
  • Neuropathic pain syndrome
  • Ischaemic pain syndrome
• Pain severity at least moderate (VAS ≥ 5) having a substantial impact on daily functioning and quality of life
• Insufficiently responding to appropriate trials of medication and/or minimally invasive treatments (such as local anaesthetic nerve blocks) and/or experiencing intolerable side effects of these treatments
• No clear benefits of surgery expected
	• Unwilling to have an implant
	• Unable to manage the device
	• Absolute contra-indications for active treatment (e.g. unfit for undergoing SCS, pregnancy, spine infection, coagulation disorder)
	• Uncontrolled disruptive psychological or psychiatric disorder
	• Ongoing alcohol and drug misuse
	• Widespread pain

Variables/categories and related definitions
Lack of engagement (no; partly; total)
Failing to attend appointments (offered by the neuromodulation or other services)
Failing to follow up on agreed recommendations, e.g. self-referral to psychological therapy service
Non-compliance with treatment
Attending treatment (e.g. a pain management programme) but with a clear lack of engagement with the programme (e.g. frequently attending late, non-participation in group tasks, not completing homework tasks/exercise programme)
Dysfunctional coping (no or mild; moderate; severe)
Avoidance of movement/activity
Avoidance, misuse of medication/illegal drugs
Unrealistic expectations (no or mild; moderate; severe)
Total pain relief
Inability to articulate post-implant goals
Inadequate daily activity level (no or mild; moderate; severe)
Inconsistency between what patient reports they can do and what they have shown they can do, e.g. patient reporting they cannot get out of bed for short period but attends all appointments
Low self-efficacy
Lack of, or very restricted, participation in activities of daily living
Problematic social support (no or mild; moderate; severe)
No social/family support
Poor quality support, e.g. patient reports they have friends/family but are unreliable, patient has not sought their support
Secondary gain (no; probably; yes or very likely)
Litigation
Presence of factors that mean that the patient might (unconsciously) have an incentive for remaining "ill"
Psychological distress/mental health problems (no or mild; moderate; severe)
For example: low mood, anxiety, panic disorder, post-traumatic stress disorder
Unwilling to reduce high-dose opioids (no, or not applicable; probably; very likely)
Use of high-dose opioids, and unwilling to reduce these to an acceptable level according to the opinion of the treating physician

Abstract: Given the differing mechanisms thought to underlie therapeutic sub- and supra-perception based neurostimulative modalities, Spinal Cord Stimulation (SCS) systems designed for combined delivery of these approaches may help improve analgesic outcomes and quality of life, and reduce treatment failures. This multicenter, observational case-series evaluated 188 patients with chronic back and/or leg pain implanted with an SCS device capable of sequential or simultaneous delivery of sub-perception and supra-perception stimulation programming (i.e., combination therapy) at 16 in Europe. Following implantation, patients were provided with an array of advanced supra-perception programs (e.g., paresthesia-based SCS using multiple independent current sources), and a custom set of sub-perception programs optimized with specific waveforms and/or field shapes. A mean overall pain score of 7.9 ± 1.7 (Standard Deviation (SD)) was reported pre-trial (Baseline). Overall pain was reduced by 4.4 ± 2.8 points (NRS) at 3-months (n = 117) and at 12 months post-implant (n = 90), respectively ($p < 0.0001$). Substantial quality-of-life (EQ-5D-5L) improvement as assessed at last follow-up was also observed (n = 60). These results suggest that an implanted SCS device capable of combination therapy, while also enabled with patient-specific waveform optimization and stimulation field targeting capabilities, can enable highly effective pain relief and improve quality of life in patients suffering with chronic pain.

Pain mapping software used to assess pain surface and pain coverage where the patient could draw different painful zones. The pixels in the patient drawing are then converted into cm2, using several anatomical landmarks, patient morphology and morphometry. Four colors are available for patients to represent the different pain intensities. Pain coverage can then be obtained by drawing paresthesia (in green), which is converted to a percentage of pain coverage (performance).

Comparisons of percentage of pain intensity decrease, percentage of pain surface decrease and paresthesia coverage between the "loss of coverage" group (n = 11) and the "SCS tolerance" group (n = 16).

Variable	LoC Group (n = 11)	SCStol Group (n = 16)	p-Value
Age	54.6 ± 11.6	52.2 ± 11.8	0.68
Sex			0.76
Male	7 (63.6%)	8 (50.0%)	
Female	4 (36.4%)	8 (50.0%)	
Duration between SCS implantation and adapter rescue therapy (years)	6.4 ± 5.1	5.6 ± 5.4	0.73
1-month follow-up	n = 10	n = 9	
Percentage of VAS decrease	32.56 ± 41.81	26.13 ± 33.33	0.60
Percentage of pain surface decrease	64.3 ± 33.86	11.77 ± 65.81	0.034
Paresthesia coverage	73.88 ± 35.77	27.6 ± 32.99	0.048
3-month follow-up	n = 8	n = 8	
Percentage of VAS decrease	36.89 ± 29.98	31.75 ± 39.61	0.75
Percentage of pain surface decrease	47.01 ± 38.69	20.13 ± 69.85	0.047
Paresthesia coverage	55.57 ± 46.23	30.5 ± 47.49	0.35
6-month follow-up	n = 8	n = 10	
Percentage of VAS decrease	50.56 ± 31.83	36.36 ± 43.69	0.59
Percentage of pain surface decrease	34.47 ± 44.77	18.13 ± 64.32	0.60
Paresthesia coverage	51.25 ± 48.66	38.56 ± 52.7	0.92
12-month follow-up	n = 8	n = 8	
Percentage of VAS decrease	58.68 ± 32.79	35.77 ± 44.09	0.19
Percentage of pain surface decrease	51.32 ± 42.31	26.61 ± 54.39	0.21
Paresthesia coverage	63.62 ± 46.26	21.5 ± 47.25	0.14

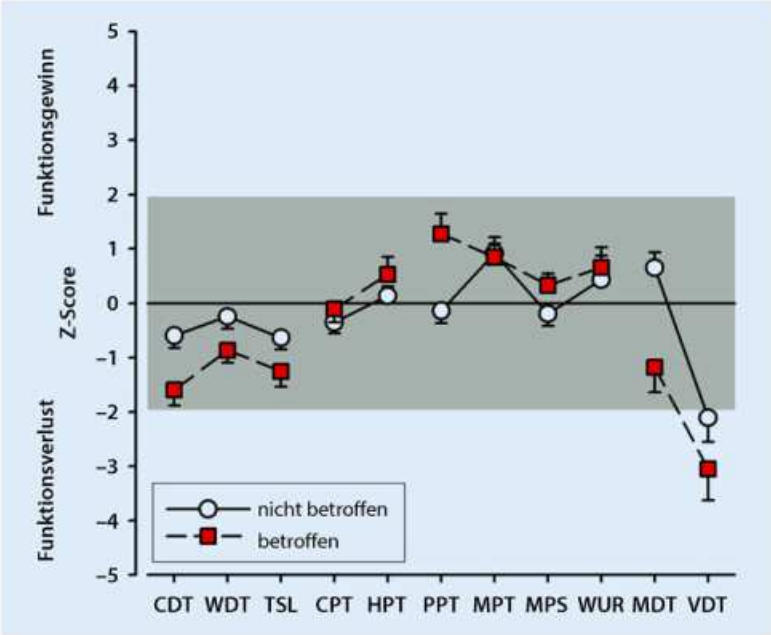
Bild eines chronischen komplexen regionalen Schmerzsyndroms
(CRPS) des linken Fußes mit ausgeprägten trophischen Störungen mit Ver-
änderung des Hautkolorits und Ödem

Rebhorn C., Dimova V., Birklein F., Komplexes regionales Schmerzsyndrom – ein Update. Schmerz 2022. 36:141-149.



Ein typisches QST(quantitativ sensorische Testung)-Profil (n = 50) von akuten CRPS(komplexes regionales Schmerzsyndrom)-Patienten: Auf der Y-Achse sind Z-Werte, d. h. Standardabweichungen von Gesunden, abgetragen; der Mittelwert ist normiert auf 0. Die roten Symbole stellen die betroffene Seite dar, die offenen Kreise die gesunde Seite. Auf der kranken Seite haben Patienten mit CRPStypischerweise eine thermische Hypästhesie (Kaltschwelle [„cold detection threshold“, CDT], Warmschwelle [„warm detection threshold“, WDT], Kombination [„thermal sensory limen“, TSL]), der Z-Wert ist niedriger als auf der gesunden Seite. Daneben findet sich eine mechanische Hyperalgesie (Druckschmerzschwelle [„pain pressure threshold“, PPT]), der Z-Wert ist größer. Nicht schmerzhafte mechanische Reize mit Von-Frey-Haaren („mechanical detection treshold“, MDT) werden weniger wahrgenommen. Die Vibration („vibration detection treshold“, VDT) wird beidseits weniger gespürt, was sich aber bei vielen chronischen Schmerzerkrankungen findet und aufmerksamkeitskorreliert sein dürfte. CPT „current perception threshold“, HPT „heat pain threshold“, MPT „mechanical pain threshold“, MPS „mechanical pain sensitivity“, WUR „wind-up ratio“

Rebhorn C., Dimova V., Birklein F., Komplexes regionales Schmerzsyndrom – ein Update. Schmerz 2022. 36:141-149.
